SOEPpapers on Multidisciplinary Panel Data Research at DIW Berlin

This series presents research findings based either directly on data from the German Socio-Economic Panel study (SOEP) or using SOEP data as part of an internationally comparable data set (e.g. CNEF, ECHP, LIS, LWS, CHER/PACO). SOEP is a truly multidisciplinary household panel study covering a wide range of social and behavioral sciences: economics, sociology, psychology, survey methodology, econometrics and applied statistics, educational science, political science, public health, behavioral genetics, demography, geography, and sport science.

The decision to publish a submission in SOEPpapers is made by a board of editors chosen by the DIW Berlin to represent the wide range of disciplines covered by SOEP. There is no external referee process and papers are either accepted or rejected without revision. Papers appear in this series as works in progress and may also appear elsewhere. They often represent preliminary studies and are circulated to encourage discussion. Citation of such a paper should account for its provisional character. A revised version may be requested from the author directly.

Any opinions expressed in this series are those of the author(s) and not those of DIW Berlin. Research disseminated by DIW Berlin may include views on public policy issues, but the institute itself takes no institutional policy positions.

The SOEPpapers are available at

Growing up in Ethnic Enclaves: Language Proficiency and Educational Attainment of Immigrant Children^{*}

Alexander M. Danzer, Carsten Feuerbaum, Marc Piopiunik, and Ludger Woessmann[†]

Abstract

Does a high regional concentration of immigrants of the same ethnicity affect immigrant children's acquisition of host-country language skills and educational attainment? We exploit the exogenous placement of guest workers from five ethnicities across German regions during the 1960s and 1970s in a model with region and ethnicity fixed effects. Our results indicate that exposure to a higher own-ethnic concentration impairs immigrant children's host-country language proficiency and increases school dropout. A key mediating factor for this effect is parents' lower speaking proficiency in the host-country language, whereas inter-ethnic contacts with natives and economic conditions do not play a role.

Keywords: immigrant children, ethnic concentration, language, education, guest workers

1. Introduction

With the recent arrival of large numbers of refugees in Europe, many societies wonder about the best policies to integrate immigrants. One central issue is the regional allocation of immigrants. To prevent ethnic ghettoization, many European countries adopted dispersal policies that assign refugees across regions (Dustmann et al., 2017). Existing evidence tends to suggest, though, that enclaves may in fact facilitate the labor-market integration of immigrants (Schüller, 2016), presumably through positive network effects within ethnic groups (Dustmann et al., 2016). However, for the successful integration of immigrants into host-country societies in the long run, the intergenerational effects of ethnic concentration on the immigrants' children seem even more important. To that extent, immigrant children's proficiency in the host-country language and their educational attainment play a particular role for long-term employment opportunities and for cultural and social integration (Dustmann and Glitz, 2011; Chiswick and Miller, 2015). On the one hand, children's language acquisition and educational integration may benefit from ethnic enclaves that provide useful information, reduced discrimination, and positive role models. On the other hand, immigrant children may also be hindered by limited exposure to native children, reduced options for language acquisition, lower socioeconomic opportunities of families, and negative role models. In this paper, we study the effect of regional ethnic concentration on the language proficiency and educational attainment of immigrant children.

Our analysis exploits the placement policy of the German guest-worker program. Between 1955 and 1973, the German government actively recruited (mainly low-skilled) foreign workers to fill labor shortages. The guest workers were enlisted in various countries of origin and then quasi-exogenously placed across West German firms. The German Socio-Economic Panel (SOEP) allows us to extract a sample of roughly 1,000 children whose parents immigrated into Germany from five different countries of origin during the period of the guest-worker program. In contrast to administrative datasets, the SOEP household panel provides information on these children's host-country language proficiency, as well as their educational attainment. In addition, the SOEP contains rich information on parents' speaking and writing abilities, friendships with Germans, and indicators for parents' social and labor-market integration that allows us to analyze factors that may mediate the effect of ethnic concentration on child outcomes. We merge the SOEP data on individual immigrant children with administrative data on the regional concentration of different ethnicities.

The initial regional assignment of guest workers provides us with plausibly exogenous variation in ethnic concentration across regions, circumventing bias from endogenous sorting of immigrants into enclaves of co-ethnics. We show that demographics of guest-worker parents and their children are balanced across regions with low and high ethnic concentration. To account for any type of region-specific or ethnicity-specific differences, our models additionally include region and ethnicity fixed effects. Region fixed effects ensure that any region-specific peculiarities are accounted for to the extent that they are common across guest-worker ethnicities. Ethnicity (country-of-origin) fixed effects ensure that any ethnicity-specific differentials in integration are accounted for to the extent that they are common across regions. Thus, we identify the effect of ethnic concentration on immigrant children's host-country language proficiency and educational attainment by observing different (exogenously placed) immigrant groups who are exposed to differential concentrations of co-ethnics within the same region, thereby circumventing bias from endogenous location choices of immigrants and from unobserved factors such as differing baseline willingness or disposition to integrate of different ethnic groups.

Our results indicate that growing up in ethnic enclaves significantly reduces immigrant children's proficiency in the host-country language and their educational attainment. In particular, a one log-point increase in the size of the own ethnic group in the region – equivalent, e.g., to increasing an ethnicity's share in the regional population from 1.0 percent to 2.8 percent – leads to a reduction in the German speaking proficiency of the children of the guest-worker generation by 19 percent of a standard deviation and a reduction in the German writing proficiency by 17 percent of a standard deviation. In addition, a one log-point increase in exposure to own-ethnic concentration increases the likelihood that the immigrant child drops out of school without any degree by 5.6 percentage points (compared to an average of 7.1 percent). Although less robust, there is some indication that ethnic enclaves also reduce the probability of obtaining an intermediate or higher school degree. Concerning effect heterogeneities, we find that effects tend to be larger for those immigrant children who were born abroad, whereas there are no significant gender differences.

Importantly, the rich background information on children and parents contained in the SOEP allows us to analyze several mediating factors. Potential mechanisms underlying the negative effect of growing up in ethnic enclaves include parents' lower host-country language proficiency, reduced interactions with natives, and lower wages and employment opportunities of immigrant parents. We find that differences in parents' ability to speak the German language – which is strongly related to their children's German language proficiency – can in fact account

for much of the effect of growing up in ethnic enclaves. In particular, once parental German speaking abilities are controlled for, the estimated effect of ethnic concentration on children's language proficiency is reduced to close to zero. For this analysis, it proves essential to address measurement error in the self-reported parental language measure by implementing an instrumental variable (IV) approach that uses parents' responses on the same survey item from consecutive years (leads and lags) as instruments (Dustmann and van Soest, 2002). While measures of parental writing abilities, friendships with German children, visits from Germans at home, parental unemployment, and household income are also significantly related to immigrant children's language proficiency, they do not account for the negative effect of ethnic concentration. Furthermore, none of the investigated mechanisms can explain the negative enclave effect on school dropout.

Our results are robust to a number of sensitivity analyses. In particular, we use alternative functional forms for the measure of ethnic concentration, instrument ethnic concentration at the time of observation by the ethnic concentration observed a decade earlier, use social-security and census data to construct the ethnic concentration measure, measure ethnic concentration at different levels of regional aggregation, and account for interview mode. We also show that neither return migration nor regional migration within Germany were selective with respect to ethnic concentration.

Our paper contributes to several strands of literature. A growing literature in sociology and economics addresses the link between ethnic enclaves and the human capital acquisition of immigrant children. Grönqvist (2006) finds lower university attainments among refugees in Sweden, Cortes (2006) finds no test score disadvantages for enclave schools in the US, and Jensen and Rasmussen (2011) establish lower test scores among immigrant children in enclaves in Denmark. While these papers do not place major emphasis on addressing bias from self-selection into ethnic enclaves, Åslund et al. (2011) use a refugee placement policy in Sweden and find that the concentration of highly educated co-ethnics positively affects the achievement of immigrant students in school.

Sharing their emphasis on identification, our main contribution beyond the Swedish study lies in the target population and results. While the Swedish paper focuses on highly educated immigrants, the focus of our study is on children of low-skilled immigrants. Over a third of guest workers had left school without a degree, and only 7 percent had completed over twelve years of education (compared to 27 percent of other immigrants in Germany at the time). The comparable share in the Swedish study is 39 percent. Arguably, our study is more representative of the majority of current low-skilled migration flows to Western countries. Crucially, our

findings stand in sharp contrast to the Swedish study, which concludes that ethnic enclaves are education-enhancing. By contrast, ethnic enclaves inhibit language take-up and school graduation in the German case. Any effect of ethnic concentration may thus strongly depend on the skill level of co-ethnics in the enclave. Our analysis differs from Åslund et al. (2011) in additional ways. Their study focuses on GPA scores and on-time school graduation, whereas we use long-run panel data to assess final school graduation as economically important outcome. Importantly, our survey data allow us to investigate the underlying mechanisms in detail, yielding important insights. Finally, unlike the Swedish refugee settlement, the German guest-worker placement implied a guaranteed immigration permit, immediate placement, and an immediate job start. Location preferences of guest workers were not considered, and they were not free to change residence during a lock-in period. In this sense, the experimental setup is even stricter and cleaner in our setting.

A vast literature studies the effects of ethnic enclaves on the *economic* integration of *adult* immigrants (see Schüller, 2016, for an overview). Using dispersal policies in Sweden and Denmark, respectively, Edin, Fredriksson, and Åslund (2003) and Damm (2009) find positive network effects of ethnic concentration on immigrants' labor-market outcomes. By contrast, studying the same setting as in our paper, Danzer and Yaman (2016) and Constant, Schüller, and Zimmermann (2013) find negative effects of ethnic concentration on adult immigrants' proficiency in the host-country language and their cultural integration, respectively. In a different German setting, Battisti, Peri, and Romiti (2016) find positive short-term but negative long-term effects of ethnic concentration on labor-market outcomes, with the negative effect being related to lower human capital investments and larger job mismatch.

Beyond immigrant integration, another large literature studies the effect of spatial segregation and concentration on the economic success of racial minorities, usually finding negative effects (e.g., Cutler and Glaeser, 1997; Fryer, 2011). More generally, a growing literature studies the effect of exposure to different quality neighborhoods during childhood on children's outcomes in the short and long run (e.g., Chetty, Hendren, and Katz, 2016; Chetty and Hendren, 2018; Gibbons, Silva, and Weinhardt, 2013, 2017).

We contribute to this literature by estimating well-identified effects of growing up in low-skilled ethnic enclaves on the language proficiency and educational attainment of immigrant children and by providing a rich analysis of mediating factors. Our findings indicate that parents' limited proficiency in speaking the host-country language is a key mediating factor of the negative impact of ethnic enclaves on immigrant children's language proficiency. By contrast, limited interaction with natives and parental economic conditions do not seem to be

leading mechanisms. Overall, the opportunity to benefit from large social networks of co-ethnics may be particularly relevant for newly arriving immigrants, but less so for the long-term integration of the children of settled immigrants. More generally, most of the arguments in favor of ethnic enclaves tend to relate to the labor-market integration of adult immigrants but bear less relevance for integration beyond the labor market. Regarding the cultural and educational integration of the second generation of immigrants, our results suggest that the fear of ghettoization that underlies the dispersal policies of several European countries may not be totally misplaced.

In what follows, Section 2 provides institutional background on the German guest-worker program. Section 3 describes the SOEP household data and the administrative data used to compute ethnic concentrations. Section 4 introduces our empirical model and shows balancing of demographic characteristics across regions with low and high ethnic concentration. Section 5 presents our main results on the effect of ethnic concentration on immigrant children's outcomes. Section 6 investigates the relevance of several potential mediating factors. Section 7 provides a number of robustness analyses. Section 8 concludes.

2. Institutional Background on the German Guest-Worker Program

The German guest-worker program was one of the largest guest-worker programs worldwide. West Germany (hereafter, Germany) signed bilateral guest-worker treaties with Italy in 1955, Greece and Spain in 1960, Turkey in 1961, and Yugoslavia in 1968. During a period of rapid economic growth in the 1960s and early 1970s, increasing demand for low-skilled workers induced a massive inflow of labor migrants to fill the numerous open positions in the economy. Given that all treaties were designed to attract low-skilled and mainly young workers, the guest workers constitute a rather homogeneous immigrant population that is, on average, less educated than the German workers. Due to the severe economic recession triggered by the oil crisis, Germany stopped the recruitment of guest workers in 1973. By that time, 2.6 million foreign workers were employed in Germany, implying that 12 percent of the labor force were foreigners (Federal Employment Agency, 1974).

To take up employment, guest workers were required to hold a valid work permit (*Arbeitserlaubnisbescheinigung*). The formal process of obtaining this permit was initiated at the foreign branches of the German Federal Employment Agency in the guest-worker countries, which was similar for all source countries.¹ Potential workers were screened for basic literacy

¹ The foreign branches of the German employment agency were called *Deutsche Kommission* in Greece, Italy, and Spain, *Deutsche Verbindungsstelle* in Turkey, and *Deutsche Delegation* in Yugoslavia. Italians could later enter

and underwent medical check-ups.² Then, guest workers were matched with German employers. The employers could submit recruitment requests together with blank work contracts to their local labor offices, which forwarded them to the foreign branches after initial approval.³

German firms received almost no information about their requested workers before arrival and in practice generally could not select workers based on job skills or country of origin (Feuser, 1961; Fassbender, 1966; and Voelker, 1976). Successful applicants got a work contract from a specific German company and a one-year work permit that was only valid for employment at the specific firm (Feuser, 1961). Recruited workers were then transferred to Germany in groups.⁴ After having stayed with their initial employer for at least two years and in the same occupation (and, in practice, in the same region for most guest workers) for at least five years, guest workers could receive an upgrade of their work permit (*Erweiterte Arbeitserlaubnisbescheinigung*) that included free job choice (Dahnen and Kozlowicz, 1963).⁵

Given that the initial location in Germany depended on current labor demand, the initial location was exogenous from the perspective of an individual guest worker. Most importantly, the guest-worker recruitment process generated exogenous variation in ethnic concentrations that allows us to estimate the causal effect of ethnic concentration on immigrant children's outcomes. The regional variation in ethnic concentration differed across ethnicities for at least three reasons. First, regional labor demand fluctuated over time, and guest-worker recruitment started in the different countries of origin at different points in time. For instance, the relative size of the guest-worker population in North Rhine-Westphalia declined between 1962 and 1973, whereas the share of guest workers in Lower Saxony and Bremen increased (Federal Employment Agency, 1964). Second, labor supply in the countries of origin varied over time.

Germany more freely within the European Economic Community (EEC) framework, but were placed by an internal recruitment branch within Germany (*Zentralstelle für Arbeitsvermittlung*). The German embassy in Yugoslavia opened a second track for guest-worker applications in 1970 to account for the high number of applicants. For more details, see Dohse (1981) and Federal Employment Agency (1962).

² At this occasion, applicants also received information on the working and living conditions in Germany. Guest workers were predominantly low-skilled due to the nature of labor demand in the construction, mining, metal, and ferrous industries at that time and because the governments of the sending countries preferred emigration from underdeveloped and disaster-ridden areas (Pennix and Van Renselaar, 1976).

³ The local labor office checked whether German workers were available for the open positions, whether housing was available for foreign workers, and whether the request fulfilled all conditions of the bilateral treaty.

⁴ Travel costs were covered by recruiting firms by paying a small flat fee for each recruited worker.

⁵ As an alternative recruitment process, employers were allowed to request guest workers by name if there was a personal relationship to that person, for example, through recommendations by relatives or friends who were already employed at that firm. Recruitment by name became more important as guest workers recommended their spouses. However, for various reasons, a large fraction of individuals who were requested by name were eventually not hired (Federal Employment Agency, 1972).

More guest workers were recruited from countries that had temporarily abundant labor supply, like Turkey in 1964 (Federal Employment Agency, 1965). Third, while guest workers from Spain and Portugal arrived by train in Cologne in the West, the port of entry for the remaining guest-worker groups (Greek, Italian, and Turkish) was Munich in the South, generating additional variation in the ethnic concentration across nationalities.

In 1973, the guest-worker recruitment was officially stopped. However, immigration of family members within the family reunification framework ensured high levels of inflows from guest-worker countries also afterwards. Those family members immigrated on the basis of the *Aliens Act* of 1965 and were granted a residence permit when joining a guest-worker family member.

3. Data

Our analysis uses individual-level information on guest workers and their children from the German Socio-Economic Panel (Section 3.1). We construct our main measure of ethnic concentration from a large employee sample of the Research Institute of the Federal Employment Agency (Section 3.2).

3.1 Survey Data on Guest Workers and their Children

We use information on guest workers and their children from the German Socio-Economic Panel (SOEP, version 30), a large annual household survey that is representative of the resident population in Germany (Goebel et al., 2018). The first SOEP wave in 1984 strongly oversampled guest workers (by a factor of four). As a consequence, 1,393 of the 5,921 SOEP households originated from the five guest-worker countries, which comprised the largest foreigner populations in Germany at the time (Sample B). For each ethnicity, an independent random sample was drawn to allow for stand-alone analyses (Haisken-DeNew and Frick, 2005). The SOEP contains detailed information on individual characteristics, including educational attainment and, for foreigners, self-reported German speaking and writing proficiency.⁶ The 1985 survey is the first wave that provides sufficient geographic information on the region of residence at the county level. Hence, we identify guest workers and their region of residence based on information in the 1985 wave. Using information from mothers' birth biography and pointers to their partners in 1985, we link parents to their children.⁷ While the SOEP does not

⁶ All questionnaires, in German and partly in English, are available at https://www.diw.de/en/diw_02.c.222729.en/questionnaires.html.

⁷ We use only children for whom both mother and father could be identified.

contain a direct indicator of guest workers, we identify guest workers by their country of origin, year of immigration, and age at migration. The guest-worker immigration differed from previous immigration experiences in Germany in that guest workers were predominantly male, young, and low educated.⁸

Our analysis sample consists of 1,065 guest-worker children with Greek, Italian, Spanish, Turkish, or Yugoslav background. To be included in the sample, children must have at least one parent who was aged 18 or older at immigration and who arrived in Germany during the period when the guest-worker program with her/his home country was in place. We restrict the sample to children aged 13 or younger at migration since the focus of our study is to investigate the impact of the region where children grow up.⁹ We keep only children with at least one observation for self-reported German language proficiency or one observation for educational attainment.¹⁰

We measure children's German language proficiency by two distinct outcomes: speaking proficiency and writing proficiency. Both language outcomes are self-reported and based on the following question: "In your opinion, how well do you speak and write German?" Answers are provided on a five-point scale: very well, well, fairly, poorly, and not at all. Children report their German language proficiency for the first time at the age of 17 or 18, i.e., when they are personally interviewed in the SOEP for the first time. An advantage of the panel data is that we observe multiple observations of self-reported language proficiency for each child (five observations per child on average), resulting in a large sample of language proficiency observations. An additional advantage of the panel data is that we can address measurement error in *parents'* language proficiency by instrumenting the self-reported language proficiency in a given year with their self-assessments in previous or succeeding years (see Section 6.1). In our sample of language proficiency, each observation is at the child-year level. This sample is based on the SOEP waves 1984-1987, 1989, 1991, 1993, and every two years from 1997 to

⁸ Appendix Table A1 compares demographic characteristics of guest workers and immigrants from other countries in 1985, based on all first-generation immigrants in the SOEP. Guest workers are, on average, five years younger and more likely to be employed in 1985, consistent with their demand-driven recruitment. Guest workers have around two years less education. Most strikingly, while 36 percent of guest workers have left school without any type of school degree, this share is only 3 percent among other immigrants. Only 7 percent of guest workers have more than 12 years of schooling, compared to 27 percent of immigrants from other countries.

⁹ We present heterogeneity results below for guest-worker children born in Germany vs. children born abroad.

¹⁰ The main reason for missing values on language proficiency and educational attainment is that households stopped participating in the SOEP survey before the children turned 17 years old and would be personally interviewed for the first time. The share of children with missing values on the outcomes does not differ between regions with low and regions with high co-ethnic concentration (see bottom of Table 1).

2005, including about 4,900 child-year observations.¹¹ We standardize each outcome of children's language proficiency to have mean 0 and standard deviation 1.

Children's educational attainment is also measured by two variables. The binary indicator "any school degree" equals 1 if the child obtained any type of school degree and 0 if the child dropped out of school without any degree. The binary indicator "at least intermediate school degree" equals 1 if the child obtained an intermediate school degree (*Realschulabschluss*) or a higher secondary school degree and 0 otherwise.¹² Children's educational attainment is based on the most recent available information in the SOEP.¹³

Table 1 reports descriptive statistics of children's outcomes and demographic characteristics of children and their parents, separately for regions with low and high ethnic concentration (split at the ethnicity-specific median of the share of ethnic concentration in 1985). Immigrant children living in regions with a high co-ethnic concentration report lower German speaking proficiency (statistical significance at 12 percent) and lower writing proficiency (significant at the 10 percent level) than immigrant children living in low co-ethnic concentration regions. Consistent with this finding, immigrant children in regions with high co-ethnic concentration are significantly less likely to obtain a school degree and slightly (and statistically insignificantly) less likely to obtain at least an intermediate school degree.

In terms of ethnicities, 37 percent of immigrant children in our sample are Turkish, 19 percent each are Italian and Yugoslav, 15 percent are Greek, and 10 percent are Spanish. We identify the ethnicity of the immigrant children primarily based on their first citizenship (94.2 percent of the children in our sample). In the case of a German citizenship or missing citizenship information, ethnicity is based on the children's country of birth or their parents' nationality (see Appendix Table A2 for definitions of all individual-level variables).¹⁴ A slight majority of immigrant children in the sample (57.1 percent) were born in Germany. The average year of birth is 1971, and the average age at migration is 2.8 years.

¹¹ Our panel data set for children's language proficiency is unbalanced for two reasons. First, some children were younger than age 17 in 1985 and therefore did not participate in the personal interviews during the first years of our panel data. Second, some children (usually the entire household) left the SOEP survey before 2005.

¹² In Germany, there are three types of secondary school degrees: basic (*Hauptschulabschluss*), intermediate (*Realschulabschluss*), and advanced (*Abitur*). A small share of children in our sample (2.9 percent) reported to have obtained another type of school-leaving certificate. While we assume that this other type of school-leaving certificate is equivalent to an intermediate school degree, the results do not depend on this assumption.

¹³ If the most recent available information indicates dropout or no school degree (yet), we checked for school-leaving degrees reported in previous waves. For only nine children, we adjusted the educational attainment variables based on previously reported school-leaving degrees.

¹⁴ In the very few instances in which children have a German citizenship or information on citizenship is missing and the nationality of mother and father differs, we use mother's nationality or mother's country of birth.

The SOEP also contains a rich set of additional individual characteristics, including the immigration history, educational attainment, and labor-market outcomes of adults.¹⁵ This wealth of information allows us to investigate several potential mediating factors that may drive the effects of ethnic concentration. As potential mediating factors, we investigate parents' speaking and writing proficiency in German, parents' employment status, household income, visits from Germans at home, and whether the child's first friend is German. Parents' mediating factors are based on the average of mothers' and fathers' information.

3.2 Ethnic Concentration

We compute measures of the concentration of co-ethnics in the region separately for the five guest-worker nationalities (Greek, Italian, Spanish, Turkish, and Yugoslav) at the regional level of the so-called *Anpassungsschichten*. Typically, these regions comprise several counties and constitute a regional labor market. In West Germany (incl. West Berlin), there were 103 *Anpassungsschichten* in 1985 with an average population of about half a million people. Allowing for sorting within large regions, this level of regional aggregation produces conservative estimates and circumvents potential bias from the typical sorting of immigrants into close-by cities or across city districts (Danzner and Yaman, 2016).

For the measurement of ethnic concentration, we use the Sample of Integrated Labor Market Biographies (*Stichprobe der Integrierten Arbeitsmarktbiografien*, SIAB) of the Research Institute of the Federal Employment Agency (*Institut für Arbeitsmarkt- und Berufsforschung*, IAB). The SIAB is a 2 percent random sample of all individuals in Germany who are employed subject to social security, job seeking, or benefit recipients as contained in the Integrated Employment Biographies of the German social security system (Dorner, König, and Seth, 2011). We use data from 1985, the year when guest workers' region of residence is observed for the first time in the SOEP data.

Ethnic concentration, our key explanatory variable, is measured by the logarithm of the size of the ethnic community in the region of residence in 1985 (see Appendix Table A3 for definitions of regional variables). In our regression analyses, region fixed effects control for the size of the overall population in a region. While it is common to measure ethnic concentration

¹⁵ As is typical for surveys, our data on guest workers and their children contain missing values for some variables. Since our set of control variables is large, dropping all children with any missing value would substantially reduce the sample size. We therefore impute missing values by using the mean of each control variable. For binary indicators, imputed means are rounded to the closest integer. To ensure that results are not driven by imputed values, all our estimations include imputation dummies for each variable. The share of imputed values is small for all imputed variables on demographic characteristics (at most 3.6 percent). The main results are similar when excluding all observations with imputed values.

as the log size of the own ethnicity (e.g., Edin, Fredriksson, and Åslund, 2003; Damm, 2009; Åslund et al., 2011), below we also report the robustness of our results to using the share of the own ethnicity in the total regional population as an alternative measure (e.g., Chiswick, 2009; Danzer and Yaman 2013, 2016). We match our measures of ethnic concentration to the individual-level SOEP data at the level of regions (*Anpassungsschichten*) and ethnicities.

The extensive demand-driven recruitment of guest workers generated substantial variation in ethnic concentrations across regions. Figure 1 shows the distribution of ethnic concentrations separately for each of the five ethnicities across the 103 West German regions (*Anpassungsschichten*) in 1985 (see Appendix Table A4 for descriptive statistics). There are clear differences in the settlement structures between the guest-worker ethnicities. For example, while Spanish guest workers tend to be concentrated in central Germany, Italians and Yugoslavs are more concentrated in the southern regions. We exploit the differential concentrations of ethnicities across regions in our analyses by using only differences in ethnic concentrations within the same region.

For robustness analyses, we also use the 1987 German Census to compute alternative measures of ethnic concentration. Being based on a 2 percent employee random sample, the SIAB measure of ethnic concentration may contain classical measurement error, biasing our estimates toward zero. In addition, if the regional share of co-ethnics in the employee sample does not reflect the ethnic concentration in the overall population – for example, because of differential labor-market participation rates – there may be non-classical measurement error. In robustness analyses, we therefore also use an alternative measure of ethnic concentration based on data from the 1987 Census. An advantage of this alternative measure is that the 1987 Census includes the entire population in Germany. The depth of the Census data also allows us to perform robustness analyses that define ethnic enclaves at the level of the 328 West German counties. A major disadvantage of the 1987 Census is that it does not allow to compute ethnic concentrations for Spanish guest workers, which reduces the sample size and excludes one of the five guest-worker ethnicities.¹⁶ In addition, the ethnicity measure in the Census is based on citizenship information (as country of birth is not observed in the Census), and the 1987 Census measures ethnic concentrations two years later than the 1985 SIAB data. Appendix Figures A1 and A2 depict the distribution of the Census-based measures of ethnic concentration separately for the four ethnicities at the level of *Anpassungsschichten* and counties, respectively.

¹⁶ Individuals with Spanish citizenship are included in the category “other citizenship.” In the SOEP data, Spanish guest-worker children make up about 10 percent of the analysis sample.

4. Empirical Model

In this section, we discuss the basic setup of our empirical model (Section 4.1) and show the balancing of demographic characteristics of guest workers and their children across regions with low and high concentrations of co-ethnics (Section 4.2).

4.1 Model Setup with Region and Ethnicity Fixed Effects

We aim to estimate the effect of ethnic enclaves on the language proficiency and educational attainment of immigrant children. Exploiting the quasi-exogenous placement of guest workers, our basic model setup expresses immigrant children's outcomes as a function of the concentration of their ethnicity in their region. Conditioning on fixed effects for ethnicities and regions, the model is identified from the concentration of an ethnicity in a particular region compared to the concentration of other guest-worker ethnicities in the same region.

When estimating the effect of ethnic enclaves on immigrant children's host-country language proficiency, we make use of the panel structure of the SOEP where immigrant children report their German language proficiency in multiple consecutive years. This allows estimating the following random effects model:¹⁷

$$lang_{i,t} = \beta_0 + \beta_1 EC_i + \mathbf{C}_i' \beta_2 + \mathbf{P}_i' \beta_3 + \delta_r + \sigma_c + \tau_t + \mu_i + \epsilon_{i,t} \quad (1)$$

where $lang_{i,t}$ is the German speaking and writing proficiency, respectively, of child i in year t . The key explanatory variable is the concentration of child i 's ethnicity in her region, EC_i .¹⁸ $\mathbf{C}_i$ is a vector of child characteristics, including gender, year of birth, and age at migration. $\mathbf{P}_i$ is a vector of parent characteristics, including year of birth, year of arrival in Germany, education in country of origin, years of schooling, a migration indicator (which equals 0 for a few spouses who have no migration background),¹⁹ and the number of children for mothers. All models include fixed effects for regions, δ_r , fixed effects for ethnicities (countries of

¹⁷ Just like a pooled OLS estimation, the random effects model effectively uses the average language proficiency across all observed time periods. In contrast to pooled OLS estimation (which underestimates the standard errors), however, the random effects model takes into account the positive serial correlation of the composite error, $\mu_i + \epsilon_{i,t}$. Still, random effects and pooled OLS regressions yield very similar results.

¹⁸ As described in Section 3.2, ethnic concentration, EC_i , is measured as the (log) size of child i 's ethnic community in her region of residence in 1985, the first year in which the SOEP provides sufficient geographical information on guest workers. Including the quadratic of EC_i does not indicate any non-linearities in the effects of ethnic concentration on language proficiency or school dropout, speaking against the existence of crucial thresholds or tipping points.

¹⁹ Among the parents in our sample, 2.9 percent of mothers and 0.8 percent of fathers are of German nationality without migration background.

origin), σ_c , and fixed effects for the year when the child reported her language proficiency, τ_t . The individual-specific effects, μ_i , are assumed to be i.i.d. random variables, and $\epsilon_{i,t}$ is an idiosyncratic error term. Throughout, we cluster standard errors at the region-by-ethnicity level, the level at which our measure of ethnic concentration varies.

To estimate the effect of ethnic concentration on immigrant children's educational attainment, we estimate the following OLS model using a cross-section of children:

$$educ_i = \theta_0 + \theta_1 EC_i + \mathbf{C}_i' \theta_2 + \mathbf{P}_i' \theta_3 + \delta_r + \sigma_c + \epsilon_i \quad (2)$$

where $educ_i$ is the educational attainment of child i , measured either by a binary indicator for having obtained any school degree or by a binary indicator for having obtained at least an intermediate school degree. As in equation (1), we include controls for child and parent characteristics as well as region and ethnicity fixed effects.

By including ethnicity fixed effects, we account for any differences between ethnicities, such as linguistic distance to the German language, cultural distance, school quality in the country of origin, and general willingness or disposition to integrate into the host country. By including region fixed effects, we exploit only variation in ethnic concentrations within the same region, but do not use systematic differences in ethnic concentrations across regions. Thus, we control for any differences across regions, such as unemployment rates, wage levels, overall share of migrants, school quality, and attitudes of the native population. Our model therefore identifies the effect of ethnic concentration on immigrant children's outcomes from the presence of several immigrant groups with differing community sizes within the same region.

4.2 Balancing Test by Degree of Ethnic Concentration

As argued above, the placement policy of the German guest-worker program led to quasi-exogenous variation in the regional placement of guest workers. We can test this assumption by comparing observable characteristics of the immigrant children and their parents between regions with low and high ethnic concentration of the respective ethnicity. To do so, we split the sample at the ethnicity-specific median of the share of ethnic concentration in the child's region of residence in 1985. As indicated by Table 1, none of the demographic characteristics of immigrant children differs significantly (individually or jointly) across regions with low and high co-ethnic concentration. The same is true for the demographic characteristics of mothers

and fathers. These balancing tests support our assumption that there was no systematic self-selection of guest workers into regions of differing ethnic concentration.

Beyond demographic backgrounds, the only exceptions where we find a significant difference between regions with low and high ethnic concentration are fathers' unemployment rates and household income. Interestingly, guest workers are *better* off in terms of employment and income in regions with *high* shares of co-ethnic concentration. If anything, this difference should work against finding any negative effect of ethnic concentration on children's outcomes. The unemployment difference observed for guest-worker fathers in the SOEP sample is qualitatively in line with the overall unemployment rates in 1985 from the Federal Employment Agency (see bottom of Table 1). Thus, the unemployment difference likely reflects the fact that guest workers were particularly demanded in regions with booming industries, which were still characterized by lower unemployment levels in 1985. Of course, the region fixed effects in our regression models account for any general difference across regions, exploiting only within-regional variation across different ethnicities. Furthermore, as we show below, differences in unemployment and household income do not explain the effect of ethnic concentration on children's outcomes.

The balancing of guest workers' demographic characteristics across regions with low and high ethnic concentration is particularly reassuring as we observe the location of guest workers in 1985 for the first time. As we do not observe the initial location to which guest workers had been assigned, we have to assume that any movement of guest workers across regions between their arrival in the 1960s/1970s and 1985 is orthogonal to our relationship of interest. Thus, the estimated coefficient on ethnic concentration would be biased downward (upward) if parents with adverse (advantageous) characteristics related to their child's outcomes moved to regions with high ethnic concentrations. The balancing results support our identifying assumption that guest workers in Germany did *not* systematically self-select into regions between their arrival and 1985.²⁰ Further supporting this assumption, we show in Section 7.7 below that the movement of guest workers across regions in the ten years after 1985, when we can observe them, was in fact orthogonal to ethnic concentration and to our outcome measures.

This is in line with existing work investigating the German guest-worker program. Previous studies also did not find any evidence of significant differences in demographic characteristics

²⁰ Alternatively regressing the *continuous* measure of the share of ethnic concentration on each demographic characteristic (including region and ethnicity fixed effects) yields only statistically insignificant coefficients, except for a significant positive coefficient on the variable indicating that parents had no schooling. In contrast, the coefficients on all four outcome variables are negative and statistically significant at about the one percent level (results available upon request).

between guest workers living in regions with high concentrations of co-ethnics and those living in regions with low concentrations (Constant, Schüller, and Zimmermann, 2013; Danzer and Yaman, 2013, 2016). In contrast to the settings studied in some other papers (such as refugees in Sweden in Åslund et al., 2011), the evidence against endogenous sorting of immigrants into ethnic enclaves in our setting is perfectly consistent with two specific features of the German guest-worker program.

First, as discussed above, guest workers were restricted in their residential choice as their work permit required them to stay in the initially assigned region for several years (Dahnen and Kozłowicz, 1963). Thus, the formal rules of the guest-worker program made it hardly possible for guest workers to move across regions during the initial years after their arrival.

Second, guest workers in Germany were well integrated into the labor market immediately upon arrival as they had been recruited specifically for the purpose to fill open positions in the German economy. As a result, the unemployment rate of foreigners in Germany was less than 1.5 percent in every year between 1968 and 1973 and was even lower than that of natives (Federal Employment Agency, 1974). Since guest workers – who migrated to Germany with the aim to work – had been employed immediately upon arrival, the incentive to move to other regions was very low. Accordingly, the current settlement structures of immigrants in Germany have been shown to still reflect the demand for labor in the 1960s and 1970s (Schönwalder and Söhn, 2009). Quite generally, ethnic segregation has been reasonably stable across workplaces and residential locations over the entire period from 1975 to 2008 (Glitz, 2014).

In sum, the demographic characteristics of guest workers and their children are very similar across regions with low and high ethnic concentration. This finding supports our identification strategy of exploiting the quasi-exogenous placement of guest workers across West German regions to estimate the effect of ethnic enclaves on immigrant children's outcomes.

5. The Effect of Ethnic Concentration on Immigrant Children's Language Proficiency and Educational Attainment

This section presents our main results (Section 5.1) and subgroup analyses (Section 5.2). In the subsequent sections, we provide investigations of mediating factors and robustness analyses.

5.1 Main Results

Table 2 shows our main results on the effect of ethnic concentration on the host-country language proficiency of immigrant children. The results indicate that an increase in co-ethnic

concentration significantly reduces immigrant children's speaking and writing proficiency in German. An increase in the size of the own ethnicity by one log-point is related to a decline in speaking skills by 19 percent and in writing skills by 17 percent of a standard deviation. The magnitudes of the estimated coefficients barely change when we include controls for children's and parents' characteristics.

To facilitate interpretation of magnitudes, ethnic concentration would increase by one log-point, for example, if a Turkish child moved from the city of Bonn (with a share of Turks of about 1 percent) to the city of Munich (with a share of about 2.8 percent).²¹ This change in the region of residence would, *ceteris paribus*, reduce the child's German speaking proficiency by 19 percent and her writing proficiency by 17 percent of a standard deviation, respectively. This is a modest effect, given that the difference between "poor" and "fair" German language proficiency is 1.39 standard deviations for speaking and 1.12 standard deviations for writing.

In line with the negative impact on host-country language proficiency, we also find a negative effect of ethnic concentration on immigrant children's educational attainment (Table 3). Living in an ethnic enclave substantially increases the likelihood of the child to drop out of school without any degree (columns 1 and 2). A one log-point increase in co-ethnic concentration increases the probability of dropping out of school by 5.6 percentage points. Given that the overall drop-out rate among immigrant children in our sample is only 7.1 percent, this is a huge effect. While results also point toward a negative impact on the probability of obtaining at least an intermediate school degree, the coefficient is much less precisely estimated and becomes zero when controlling for child and parent characteristics (columns 3 and 4).²²

Both findings – the negative effect on host-country language proficiency and the negative effect on obtaining any school degree – suggest that immigrant children who grew up in regions with high shares of (low-educated) co-ethnics suffer long-term disadvantages in human capital acquisition.

5.2 Subgroup Analysis

Next, we investigate effect heterogeneity by country of birth, gender, and ethnicity.²³ We start by investigating whether the negative effects of ethnic concentration on children's

²¹ An increase in the size of the ethnic community by one log-point corresponds to an increase by 172 percent. The difference in average ethnic concentration between low ethnic concentration and high ethnic concentration regions is 1.19 log-points.

²² Similarly, there is no evidence for a significant effect of ethnic concentration on obtaining an advanced school degree (*Abitur*) (not shown).

²³ Analysis of effect heterogeneity by parents' educational background does not produce significant differences.

outcomes differ between children born abroad and children born in Germany. About 42 percent of the immigrant children in our sample were born abroad, entering Germany through a family reunification scheme. The first two columns of Table 4 suggest that the negative enclave effects on German speaking and writing proficiency are roughly 30 percent smaller for children who were born in Germany rather than abroad. As children born in Germany start learning the German language already in kindergarten and school, co-ethnic concentration may be less important for them compared to children born abroad who typically start learning the German language at an older age. Still, the ethnic-concentration impact is also significant for guest-worker children who were born in Germany. Furthermore, the smaller negative impact on the host-country language proficiency of children born in Germany does not translate into a smaller disadvantage in terms of dropping out of school (column 3).

The right panel of Table 4 investigates effect heterogeneity by child gender. Results indicate that the impact of ethnic concentration on children's language proficiency and educational attainment does not differ significantly between boys and girls, although the negative effect on school dropout may be slightly smaller (in absolute terms) for girls.

Subgroup analyses by ethnicity indicate little heterogeneity (Appendix Table A5). Results suggest that the effect of ethnic concentration on German speaking and writing proficiency and on school dropout does not differ significantly for Greek, Italian, Spanish, Turkish, or Yugoslav guest-worker children. There is some indication, however, that ethnic concentration may have a more negative effect on the probability of obtaining at least an intermediate school degree for Italian and Turkish children, and a more positive one for Greek and Spanish children.

6. Mediating Factors

The effect of ethnic enclaves on immigrant children's outcomes may be mediated through numerous different channels, including parents' language skills, inter-ethnic contacts with natives, and economic conditions. Existing studies that rely on administrative data are usually restricted to looking at the enclave effect as a black box. By contrast, the rich SOEP survey data allow us to investigate several potential mediating factors at the child and parent level.

6.1 Parental Proficiency in the Host-Country Language

A first candidate for a mediating factor is parents' host-country language skills, as children's human capital accumulation may critically depend on the language proficiency of their parents. In fact, Danzer and Yaman (2016) find a strong negative effect of ethnic enclaves on the language skills of first-generation guest workers in Germany. In the SOEP, adult guest

workers report their German language proficiency in speaking and writing similar to their children. Using the same random effects specification (without child controls) and the same definitions for language proficiency and ethnic concentration as in our main model, we find an effect of ethnic enclaves on the speaking proficiency of parents of -0.351 (standard error 0.081), but no significant effect on parents' writing proficiency (-0.072, standard error 0.091).

Table 5 adds different potential mediating factors as control variables to our main model for children's German speaking proficiency.²⁴ As indicated in column 2, parents' German speaking proficiency is significantly positively related to their children's German speaking proficiency. Controlling for parents' German speaking proficiency reduces the effect of ethnic concentration and renders it statistically insignificant, although the negative point estimate remains quite sizeable. However, self-assessed language proficiency is likely measured with error. To circumvent downward bias in the estimated effect of parents' language proficiency, we follow the approach of Dustmann and van Soest (2002) and exploit the panel dimension of the SOEP to instrument parents' speaking proficiency reported in a given year with their speaking proficiency reported in preceding (lag) and subsequent (lead) years.²⁵

After accounting for random measurement error by instrumenting parents' speaking proficiency with their reported proficiency in the preceding and subsequent years, parents' German speaking proficiency can fully account for the effect of ethnic concentration on children's speaking proficiency. The IV estimate on parents' speaking proficiency (column 3) is three times as large as the OLS estimate, indicating that the latter suffers from substantial attenuation bias.²⁶ Intriguingly, once the independent-over-time measurement error is accounted for, the point estimate of the effect of ethnic concentration on guest-worker children's German speaking proficiency is reduced to close to zero. This suggests that poor parental host-country language skills in ethnic enclaves are a main driver of the enclave effect on children's host-country language proficiency.

Columns 4 and 5 present equivalent analyses for parents' writing proficiency in German. While parents' German writing skills are also significantly related to their children's German

²⁴ Missing data on the self-reported language proficiency of parents reduce the sample size by 16 percent, but this does not qualitatively affect the estimate of our main effect (see column 1).

²⁵ If one of the two instruments is missing, the missing value is imputed with the other instrument. We add an imputation dummy taking on the value of one for observations with imputed values, zero otherwise. The same applies to parents' writing proficiency. Excluding observations with imputed leads and lags of parents' language proficiency yields qualitatively similar results. Note that the IV approach solves the issue of idiosyncratic (i.e., year-specific) measurement error but does not address the issue that immigrants may systematically over- or underrate their host-country language proficiency (Dustmann and van Soest, 2002).

²⁶ The *F*-statistic of the excluded instruments in the first stage is 40.7, and it is at least 10 in all following IV specifications (Appendix Table A6).

speaking proficiency, controlling for them does not reduce the estimated effect of ethnic concentration by much.

Table 6 shows the same analyses for children's writing rather than speaking proficiency. We find similar associations of parents' German language proficiency with their children's writing proficiency as we found for children's speaking proficiency. Intriguingly, it is again only parents' *speaking* proficiency (column 3), rather than their writing proficiency (column 5), that reduces the estimated enclave effect on children's *writing* proficiency to close to zero. Thus, it appears that reduced speaking proficiency in the host-country language (and therefore likely reduced speaking of the host-country language at home), rather than limited writing proficiency in the host-country language, is a leading mechanism by which ethnic enclaves inhibit the language proficiency of immigrant children. One potential reason for the greater importance of parents' speaking proficiency is the oral communication of guest workers and their children at home. Furthermore, linguists point out that while speaking requires interpersonal communication, writing is based on structural learning (Blanche and Merino, 1989). The lack of language courses for guest workers may thus have suppressed the development of writing skills more than of speaking skills. As guest-worker parents not only have a lower average level of writing ability, but also lack the competency to self-assess this ability, the self-assessed measure of writing skills may suffer from greater measurement error (Danzer and Yaman, 2016).

While adding potential mediating factors as control variables is a purely descriptive and explorative analysis, causal mediating analysis is feasible under additional assumptions. Imai et al. (2011) propose identification of causal mechanisms that rests on two key assumptions of sequential ignorability.²⁷ The first assumption is the standard exogeneity assumption: given the (pre-treatment) control variables, the degree of ethnic concentration is assumed to be ignorable, that is, statistically independent of potential outcomes and potential mediators. The second, additional assumption is that the mediating factor is ignorable given the degree of ethnic concentration and the (pre-treatment) control variables. That is, once conditioning on the latter factors, the mediating factor is statistically independent of the potential outcomes.

Employing this causal mediating analysis, the bottom rows of Tables 5 and 6 report the fraction of the effect of ethnic concentration on the outcome of interest that is mediated through the respective mediating factor. As in the descriptive analysis, parents' speaking proficiency is

²⁷ For technical details, see Imai, Keele, and Yamamoto (2010). Hicks and Tingley (2011) implemented this approach in the Stata module "mediation."

the most important mediating factor and accounts for most of the total effect of ethnic concentration. In particular, it explains 85 percent of the impact of ethnic concentration on children's speaking proficiency and 79 percent on writing proficiency in the instrumented model (column 3). At 13 to 14 percent, parents' writing proficiency explains much less (column 5). The qualitative results of the descriptive analysis are thus confirmed in the causal mediating analysis.

6.2 Inter-Ethnic Contacts with Natives and Economic Conditions

Limited contacts to German natives may constitute a further mediating factor of the negative effect of co-ethnic concentration on children's host-country language proficiency. Prior research shows that guest workers in Germany who were placed in ethnic enclaves tend to interact less with natives (Danzer and Yaman, 2013), and reduced contact with natives may in turn affect the human capital acquisition of their children. As columns 6 and 7 of Tables 5 and 6 show, having personal contacts with natives – either measured by whether the child's first friend is German or whether parents regularly receive visits from Germans – is indeed significantly positively associated with the child's German speaking and writing proficiency.²⁸ Yet, controlling for the reduced contacts with natives does not significantly change the negative estimate of ethnic enclaves on children's host-country language skills.

Furthermore, differences in economic conditions such as parental unemployment or household income might explain the negative effect of ethnic enclaves on immigrant children's language proficiency. As column 8 of Tables 5 and 6 shows, parents' unemployment status is significantly associated with their children's host-country language proficiency in the expected way, but controlling for parental unemployment and household income does not affect the estimated effect of ethnic concentration on children's language proficiency at all. Again, qualitative results are similar in the causal mediating analysis, with none of the factors of inter-ethnic contacts and economic conditions explaining more than 10 percent of the total effect of ethnic concentration.

Similar analyses indicate that none of the mediating factors analyzed here can account for the effect of ethnic enclaves on children's schooling outcomes. As indicated in Table 7, parents' speaking ability is the only analyzed factor that is significantly associated with their children's probability to obtain a school degree. Still, controlling for parents' speaking ability does not

²⁸ The two respective SOEP questions read as follows: "What is the nationality of the first person befriended?" [German national, other national] (answered by the children) and "Have you received German visitors in your home in the last 12 months?" [yes, no] (answered by the parents).

reduce the estimated effect of ethnic concentration on whether children obtain a school degree.²⁹

In sum, the negative effect of ethnic enclaves on immigrant children's host-country language proficiency can be fully accounted for by parents' lower host-country speaking proficiency. Parents' writing proficiency explains the negative enclave effect only to a small extent. By contrast, limited contacts to natives and economic factors do not appear to be relevant mediating factors of the negative enclave effects. None of the investigated mediating factors – parents' language skills, inter-ethnic contact, and economic conditions – can account for the detrimental effect of ethnic enclaves on the schooling success of immigrant children.³⁰

7. Robustness Analyses

In this section, we show that our results are robust to measuring ethnic concentration by ethnic shares (Section 7.1), instrumenting ethnic concentration in 1985 by ethnic concentration in 1975 (Section 7.2), measuring ethnic concentration with Census data (Section 7.3), measuring ethnic concentration at the county level (Section 7.4), and accounting for interview mode (Section 7.5). We also investigate return migration (Section 7.6) and regional migration within Germany (Section 7.7).

7.1 Measuring Ethnic Concentration by Ethnic Shares

There is no strong *a priori* argument for any specific functional form of the ethnic concentration measure. At least two different specific measures of ethnic concentration have been used in the literature. In our analyses so far, we followed Edin, Fredriksson, and Åslund (2003), Damm (2009), and Åslund et al. (2011) in using the logarithm of the size of the own ethnicity. In contrast, Chiswick (2009) and Danzer and Yaman (2013, 2016) measure ethnic concentration as the share of the own ethnicity in the total regional population.

When using the share of the own ethnicity in the regional population as an alternative measure of ethnic concentration, results on guest-worker children's German speaking and writing proficiency and on school dropout are qualitatively similar to our main models (Table 8). Interestingly, the alternative concentration measure also produces significant results on the probability that guest-worker children obtain at least an intermediate school degree. Specifically, the point estimate suggests that a one percentage-point increase in the share of

²⁹ Similar analyses for obtaining at least an intermediate school degree as the child outcome do not indicate any significant enclave effects; only instrumented parental writing abilities and having a German as the first friend are significantly associated with this outcome (not shown).

³⁰ This result is robust to including all mediating factors in the regression model simultaneously (not shown).

own-ethnics in the regional population reduces the likelihood of obtaining at least an intermediate school degree by 5.1 percent.

7.2 Instrumenting Ethnic Concentration in 1985 by Ethnic Concentration in 1975

As discussed in Section 4.2, we do not observe guest workers and their region of residence before 1985. While the balancing tests indicated no evidence of self-selection of guest workers across regions with different ethnic concentrations, the extent of ethnic concentration may have changed between the end of the German guest-worker program in 1973 and the observed ethnic concentration in 1985. To account for potential endogeneity of our main explanatory variable, we can instrument a region's ethnic concentration in 1985 by the region's ethnic concentration in 1975, i.e., towards the end of the German guest-worker recruitment program (Danzon and Yaman, 2013). 1975 is the first year of the SIAB data. This IV model rules out any bias from changes in ethnic concentrations in a given region during the decade before we first observe guest workers' region of residence. For instance, if economic conditions improved between immigration and 1985 in the initial placement region of a guest worker relative to other regions, we may expect an increase in ethnic concentration in this region owing to economically motivated in-migration. In this case, the ethnic concentration observed in 1985 differs from the one at quasi-exogenous placement.

Ethnic concentration in 1975 is a very strong instrument for ethnic concentration in 1985. The F statistic on the excluded instrument in the first stage is 236 in the regressions for language outcomes and 321 in the regressions for schooling outcomes.³¹ In line with Schönwalder and Söhn (2009), this suggests that there is strong persistence in the settlement structures of guest workers between the end of the guest-worker program and 1985.

Table 9 presents the results of the IV model that uses only that part of the variation in ethnic concentration in 1985 that can be traced back to variation in ethnic concentration that already existed in 1975. For both speaking and writing proficiency, the enclave effect is somewhat stronger when instrumenting 1985 with 1975 ethnic concentration compared to the baseline model. The effect on school dropout does not change and the coefficient for obtaining at least an intermediate school degree remains insignificant. Similarly, all results on mediating factors are very similar in the IV model compared to the baseline model (not shown).

In sum, our baseline estimates are not biased by any change in ethnic concentration that occurred between 1975 and 1985. If anything, restricting the analysis to variation in ethnic

³¹ The first-stage coefficient on the size of the ethnic community in 1975 is 0.85 ($p = 0.000$) in the language sample and 0.84 ($p = 0.000$) in the schooling sample.

concentration that already existed in 1975 leads to slightly larger estimates of the detrimental effect of ethnic enclaves on immigrant children's outcomes.

7.3 Measuring Ethnic Concentration with Census Data

Measuring the size of the immigrant population based on a 2 percent random sample of employees like the SIAB can lead to attenuation bias in estimating effects of immigration measures (Aydemir and Borjas, 2011). To address potential measurement error in our preferred measure of ethnic concentration, we use data from the 1987 German Census, which includes the entire population in Germany. As the 1987 Census data do not allow identifying Spanish citizens, the Census analysis is restricted to the other four ethnicities. For each ethnicity, the correlation coefficient between our preferred 1985 SIAB measure and the 1987 Census measures of the (log) size of the ethnic community exceeds 0.96.

As the odd-numbered columns of Appendix Table A7 indicate, replacing the 1985 SIAB measure of ethnic concentration with the 1987 Census measure yields very similar results to our main specifications. Furthermore, the even-numbered columns show IV models that instrument the 1987 Census measure of ethnic concentration with the concentration of guest workers in the mid-1970s using the SIAB 1975 data. These IV estimates, which simultaneously account for measurement error and changes in regional ethnic concentration after the end of the guest-worker program, are also quite similar to the baseline results. Again, the IV estimates are somewhat larger than the non-instrumented estimates. The results on mediating factors are also unaffected when using the 1987 Census data to compute measures of ethnic concentration, both in the non-instrumented and in the instrumented model (not shown). In sum, we do not find evidence that measurement error in our ethnic concentration measure has a substantial effect on our results.

7.4 Measuring Ethnic Concentration at the County Level

Our preferred regional level for measuring ethnic concentration are the *Anpassungsschichten*, as they comprise sufficiently large regions in order to circumvent bias from commuting within regional labor markets. While the much smaller regional entity of counties may more precisely measure immigrant children's exposure to co-ethnics, they also increase concerns of bias due to commuting and moving across county borders. Still, using the 1987 Census, which includes the entire population, we can test for robustness of our results to measuring ethnic concentration at the level of 328 counties rather than 103

Anpassungsschichten. However, the guest-worker children observed in the SOEP data live in only 114 different counties, reducing the variation used in the analysis.

When measuring ethnic concentration at the county level, the effects of ethnic concentration on children's speaking and writing proficiency are very similar to the estimates when measuring ethnic concentration at the *Anpassungsschicht* level (Appendix Table A8). By contrast, the effect on obtaining any school degree becomes smaller and loses statistical significance. Besides the fact that Spanish guest-worker children are missing in the analysis, statistical power in the county-level analysis may be impaired by the fact that enclave effects are identified from fewer guest-worker children observed within the same region in the SOEP data. This likely affects in particular the analysis of school dropout, which on average is already rather low (7.1 percent). In fact, incidents of school dropout by guest-worker children are observed in only 42 of the 114 counties with guest-worker children in the SOEP. This suggests that models with county fixed effects exploit only very limited variation in school dropout.

7.5 Accounting for Interview Mode

We also show that immigrants' self-reported language proficiency is not affected by the specific interview mode used in the SOEP, such as oral face-to-face interview or written interview by mail. Therefore, the first two columns of Appendix Table A9 control for the interview mode used when guest-worker children report their levels of German language proficiency. Adding this control does not affect the estimated enclave effects on children's proficiency in speaking or writing German.

7.6 Investigating Return Migration

Acquiring host-country language skills and education is an investment decision that may depend on whether immigrants intend to stay in the host country or return to their home country (Dustmann and Glitz, 2011). To account for this possibility, columns 3-6 of Appendix Table A9 include a binary indicator that equals 1 if guest-worker parents see their future in Germany (0 otherwise).³² Adding this control variable does not affect our baseline estimates. Parents' intention to stay in Germany is positively associated with the children's outcomes, albeit statistically significantly only in the case of obtaining a school degree.

We also investigate to what extent immigrant children in our sample actually returned to their home country during the first ten years of our analysis, and in particular, whether return

³² The respective SOEP question reads as follows: "How long do you want to remain in Germany?" [up to 12 months, a few years, stay in Germany].

migration was related to ethnic concentration. Following Dustmann (2003), we use the information that individuals provide when leaving the SOEP survey. We construct a binary indicator, $return_i$, which equals one if an immigrant child left the SOEP between 1985 and 1995 reporting a move abroad, and zero otherwise.³³ To predict return migration, we use the same explanatory variables as in our main model, in particular ethnic concentration in 1985:

$$return_i = \gamma_0 + \gamma_1 EC_i + C_i' \gamma_2 + \delta_r + \sigma_c + \varepsilon_i \quad (3)$$

During the observation period 1985-1995, 94 immigrant children (8.8 percent of our sample) left the SOEP and moved abroad. However, as indicated in Appendix Table A10, moving abroad is unrelated to ethnic concentration. Likewise, moving abroad is neither significantly related to whether the immigrant children obtained a school degree nor to their speaking proficiency. Furthermore, there is also no significant interaction between ethnic concentration and the human capital measures. The result that there is no selective return migration strengthens our identifying assumptions.

7.7 Investigating Regional Migration within Germany

Our analysis requires the validity of the assumption that there was no systematic sorting of guest workers across regions between their initial placement in Germany and 1985, when we observe them for the first time in the SOEP data. While lack of data prevents us from investigating cross-regional mobility before 1985, we can analyze moving patterns after 1985, a period when overall regional mobility was higher. We find that only 6.9 percent of the 749 immigrant children who remained in the SOEP sample moved across regions between 1985 and 1995. This rather low mobility is consistent with Glitz (2014), who shows that regional ethnic concentrations were stable in Germany between 1975 and 2008.

Most importantly, ethnic concentration in 1985 does not predict whether guest-worker families moved across regions over the next ten years (Appendix Table A11). Furthermore, neither obtaining a school degree nor speaking proficiency are significantly related to moving across regional borders in the decade following 1985. These associations also do not differ significantly with the size of the ethnic concentration. In sum, the low mobility and the unsystematic moving patterns with respect to ethnic concentration support our identifying assumption that guest workers did not systematically sort across regions before 1985.

³³ It is possible that children report other reasons for attriting from the SOEP and later on return to their home country, which we would not observe.

8. Conclusion

We exploit the quasi-exogenous placement of guest workers across Germany during the 1960s and 1970s to estimate the effect of growing up in ethnic enclaves on the language proficiency and educational outcomes of immigrant children. We find that growing up in regions with higher own-ethnic concentration significantly reduces immigrant children's proficiency in the host-country language and their educational attainment. For schooling outcomes, the effect is concentrated at the lower end of the educational distribution, although there is some indication that more academic school degrees may be affected as well. The enclave effects tend to be larger for immigrant children who were born abroad.

The rich information contained in the German Socio-Economic Panel, most importantly on parents' host-country language proficiency, allows investigating several factors that might mediate the effect of ethnic concentration on child outcomes. We find that parents' German speaking proficiency completely explains the negative effect of ethnic enclaves on their children's German language proficiency. Parents' writing abilities explain only little, and contacts to natives and parents' economic conditions cannot account for the negative effect of ethnic enclaves on immigrant children's outcomes at all.

These findings imply that even children of immigrants who are well integrated into the labor market may suffer from worse human capital outcomes – host-country language proficiency and educational attainment – when growing up in regions with many, mainly low-educated, immigrants of their own ethnicity. Since the enclave effect on children's language proficiency is completely explained by parents' lower host-country language skills, our findings suggest that host-country language training for adult immigrants might have important positive spillover effects on their children. Language training for adult immigrants would complement current policies in Germany that emphasize language training for immigrant children themselves, which includes compulsory German language tests before starting school.

More generally, our results indicate that the long-run cultural and social integration of immigrants, including the next generation, may be more successful when immigrants do not live in ethnic enclaves. Concerning current policy debates about how to disperse refugees across regions, our findings suggest that avoiding the emergence of ethnic enclaves might help refugee children to learn the host-country language and to avoid school dropout.

Children	500	565			1065

Notes: Variable means by degree of ethnic concentration. Low vs. high EC split at the ethnicity-specific median of the share of ethnic concentration in 1985. P-values refer to two-sided tests with standard errors clustered at region-ethnicity level. Speaking/writing proficiency: first reported self-assessed speaking/writing ability in German (from 1="not at all" to 5="very well"), normalized to mean 0 and standard deviation 1. Any school degree: 1 if individual obtained any type of school degree, 0 otherwise. At least intermediate school degree: 1 if individual obtained at least an intermediate school degree, 0 otherwise. Household income, not employed, and unemployed refer to three-year means over 1984-1986. Information on language proficiency/school degree available: 1 if information on corresponding outcome is available in the SOEP data in at least one survey year, 0 otherwise. The F-statistic of joint significance of a regression of a high-concentration dummy on individual characteristics is 0.22 for children (p-value 0.992), 0.51 for mothers (0.865), and 3.53 for fathers (0.0005) (which includes household income). Data sources: German Socio-Economic Panel (SOEP), Institut für Arbeitsmarkt- und Berufsforschung (IAB), Federal Employment Agency (2017).

More than 12 years of education	0.07	0.27	-0.20	0.00	2709
Married	0.81	0.75	0.06	0.02	2608
Children (female individuals only)	2.45	2.03	0.43	0.00	1264
Unemployed	0.08	0.06	0.03	0.09	2657
Not employed	0.31	0.44	-0.13	0.00	2733
Household income	1632.56	1649.50	-16.94	0.74	2673
Obs.	2466	267			2733

Notes: First-generation immigrants in survey year 1985. P-values are estimated using robust standard errors.
Data source: German Socio-Economic Panel (SOEP).

Table A2: Individual-Level Variables

Variable	Description
<i>Outcomes (Children)</i>	
Speaking proficiency	Generated from self-assessed speaking ability in German (not at all = 1, poorly = 2, fairly = 3, good = 4, very well = 5), normalized to have mean 0 and standard deviation 1, <i>Random Effects Model</i> : each observation is a child-year observation based on self-reported language proficiency in the years 1984-1987, 1989, 1991, 1993, 1997, 1999, 2001, 2003, and 2005.
Writing proficiency	Generated from self-assessed writing ability in German (not at all = 1, poorly = 2, fairly = 3, good = 4, very well = 5), normalized to have mean 0 and standard deviation 1, <i>Random Effects Model</i> : each observation is a child-year observation based on self-reported language proficiency in the years 1984-1987, 1989, 1991, 1993, 1997, 1999, 2001, 2003, and 2005.
Any school degree	Binary indicator that equals 1 if individual obtained any type of school degree and 0 otherwise. Based on most recent available educational level. If the most recent available information is <i>dropout</i> , <i>no school degree</i> or <i>no school degree yet</i> , we checked for school-leaving degrees reported in previous years. In nine cases, we adjusted the educational attainment variables based on previously reported school-leaving degrees.
At least intermediate school degree	Binary indicator that equals 1 if individual obtained at least an intermediate school degree and 0 otherwise. Based on the most recent available educational level. If the most recent available information is <i>dropout</i> , <i>no school degree</i> or <i>no school degree yet</i> , we checked for school-leaving degrees reported in previous years. In nine cases, we adjusted the educational attainment variables based on previously reported school-leaving degrees.
<i>Demographics of Children</i>	
Ethnicity dummies (Greek, Italian, Spanish, Turkish, Yugoslav)	Binary indicators primarily based on children's first citizenship (94.2 %). In case of German citizenship or no available citizenship information, these indicators are based on parents' joint nationality (1.0 %) or on children's country of origin (0.3 %). If children's ethnicity is not yet available and one parent is intermarried to a German or to a foreigner with different or missing nationality, we use the citizenship of the parent with the guest-worker background as a proxy for children's ethnicity (4.4 %). Regarding rare cases, if children's ethnicity is not available and both parents are migrants but their country of origin differs, we use the mother's nationality or country of origin. In the few cases of remaining missing children's ethnicities, we base children's ethnicity on father's country of origin or nationality. For more than 98.5 % of the children in our analysis sample, children's ethnicity corresponds to the father's country of origin. We could assign an ethnicity to all children in our sample.
Age at migration	Age at migration (in years). If a child is born in Germany, the variable is coded as zero.
<i>Demographics of Parents</i>	
Migrant	Binary indicator that equals 1 if individual has a migrant background and 0 otherwise. Based on variable "migback" of the SOEP Person-related meta-dataset.
Variables on education in country of origin	Three binary indicators for <i>No schooling</i> , <i>Incomplete compulsory schooling</i> , and <i>At least compulsory schooling</i> , based on survey question "Obtained School Degree Outside Germany" in survey year 1985.

Continued on next page

Table A2 (Continued)

Variable	Description
Years of education	Amount of education or training (in years), generated variable by SOEP. Based on survey year 1985.
Never moved flat since arrival in Germany	Binary indicator equal to 1 if the individual's year of immigration is either equal to the year in which the household moved into the dwelling or is later than the year in which the household moved; 0 otherwise. Based on survey year 1985.
Children	Number of mother's children. Based on variable "sumkids" from the SOEP Birth Biography of Female Respondents.
Household income (1984-1986)	Mean of parents' adjusted household income over three years. Based on survey years 1984-1986.
Not employed (1984-1986)	Mean of an indicator for being not employed during the survey years 1984-1986.
Unemployed (1984-1986)	Mean of an unemployment dummy during the survey years 1984-1986.
<i>Mediating Factors</i>	
Speaking abilities, parents	Parents' speaking ability, generated from self-assessed speaking ability in German (not at all = 1, poorly = 2, fairly = 3, good = 4, very well = 5). Based on the average of self-reported speaking ability of the mother and the father, normalized to have a mean 0 and standard deviation 1. For language proficiency estimations: measured at the time of children's reported language proficiency. For educational attainment estimations: measured as parents' second available speaking proficiency, largely based on the second survey year of the SOEP in 1985 (99 %).
Speaking abilities, parents, IV lead + lag	Parents' speaking ability is instrumented with the corresponding lead and lag to reduce measurement error (see Dustmann and van Soest, 2002), missing leads (lags) of parents' current language proficiency are imputed with available lags (leads), all regressions include imputation dummies for imputed leads or lags of parents' language proficiency, generated from self-assessed speaking ability in German (not at all = 1, poorly = 2, fairly = 3, good = 4, very well = 5). Based on the average of self-reported speaking ability of the mother and the father, normalized to have a mean 0 and standard deviation 1. For language proficiency estimations: measured at the time of children's reported language proficiency. For educational attainment estimations: measured as parents' second available speaking proficiency, largely based on the second survey year of the SOEP in 1985 (99 %).
Writing abilities, parents	Parents' writing ability, generated from self-assessed writing ability in German (not at all = 1, poorly = 2, fairly = 3, good = 4, very well = 5). Based on the average of self-reported writing ability of the mother and the father, normalized to have a mean 0 and standard deviation 1. For language proficiency estimations: measured at the time of children's reported language proficiency. For educational attainment estimations: measured as parents' second available writing proficiency, largely based on the second survey year of the SOEP in 1985 (99 %).

Continued on next page

Table A2 (Continued)

Variable	Description
Writing abilities, parents, IV lead + lag	Parents' writing ability is instrumented with the corresponding lead and lag to reduce measurement error (see Dustmann and van Soest, 2001), missing leads (lags) of parents' current language proficiency are imputed with available lags (leads), all regressions include imputation dummies for imputed leads or lags of parents' language proficiency, generated from self-assessed writing ability in German (not at all = 1, poorly = 2, fairly = 3, good = 4, very well = 5). Based on the average of self-reported writing ability of the mother and the father, normalized to have a mean 0 and standard deviation 1. For language proficiency estimations: measured at the time of children's reported language proficiency. For educational attainment estimations: measured as parents' second available writing proficiency, largely based on the second survey year of the SOEP in 1985 (99 %).
First friend German	Binary indicator equal to 1 if a child's first friend is German. Based on the first available variable on the nationality of the first-named friend. Based on survey years 1988, 1990, 1992, 1994, 1996, 2001, 2006, and 2011.
Visits from Germans, parents	Average of the following variable of mother and father: a binary indicator equal to 1 if mother or father received visits from Germans at home during the previous 12 months. For language proficiency estimations: refers to year of children's reported language proficiency. For educational attainment estimations: refers to average of the years 1985 and 1986.
Unemployed (1984-1986), parents	Average of the following variable of mother and father: Mean of an unemployment dummy over three years. Based on survey years 1984-1986.
Household income (1984-1986), parents	Mean of parents' household income over three years (in logs). Based on survey years 1984-1986.
<i>Robustness Checks</i>	
Stay in Germany, parents	Average of the following variable of mother and father: A binary dummy indicating the intent to stay in Germany. Based on the following answer categories: "I intend to stay in Germany forever" (= 1), "I intend to stay in Germany for several years" (= 0), "I intend to leave Germany within 12 months" (= 0). Based on survey year 1985.
Interview mode	Dummies based on a variable indicating the interview mode in the corresponding survey years of self-reported language proficiency (years 1984-1987, 1989, 1991, 1993, 1997, 1999, 2001, 2003, and 2005). Based on the following answer categories: "Oral Interview", "Written Questionnaire Interviewer", "Mixed Type", "Written Questionnaire No Interviewer", "Oral And Written", "Proxy", "Third Person Present", "No Third Person Present", "Computer Assisted Personal Interviewing", "Telephone Assistance", "Written, By Mail", and "Telephone Interview".

Notes: Source (for all variables): German Socio-Economic Panel (SOEP).

Table A3: Regional Variables

Variable	Description
Size of ethnic group in 1985	Log size of ethnic community (individuals of same ethnicity) in region (<i>Anpassungsschicht</i>) of residence, 1985. Log of 1 used in rare case of zero co-ethnics in the region; all regressions include a corresponding imputation dummy. See variable <i>Region of residence</i> for details on the assignment of children to 1985 regions. Based on a two percent sample of the German employee population (incl. recipients of social transfers) from the Institut für Arbeitsmarkt- und Berufsforschung (IAB).
Size of ethnic group in 1987	Log size of ethnic community (individuals of same ethnicity) in region of residence, based on German Census 1987, regional level: <i>Anpassungsschicht</i> (Table A5) or county (Table A6). Measure not available for immigrant children with Spanish ethnicity.
Official unemployment rate 1985	Unemployment rate in the year 1985, regional level: <i>Anpassungsschicht</i> , based on county-level data from Federal Employment Agency (2017).
Region of residence (used to construct ethnic concentration measures)	The region of residence (<i>Anpassungsschicht</i> or county) is primarily based on children's 1985 region of residence (94.7 %). If children's household IDs for the year 1985 are not available, the ethnic concentration measures are based on parents' 1985 region of residence for the following scenarios: children were born after 1985 (2.1 %), children had the same household ID as their parents in 1984 (1.5 %), children migrated to Germany after 1985 (0.2 %), or children joined the SOEP in a later wave than 1985 for other reasons (1.6 %). All children in our sample could be assigned to a 1985 region.

Table A4: Ethnic Concentration by Ethnicity

	Mean	SD	Min	Max
Greek	0.95	0.63	0.06	2.25
Italian	1.51	0.95	0.16	4.03
Spanish	0.39	0.24	0.00	0.97
Turkish	3.05	1.20	0.29	6.19
Yugoslav	2.06	1.21	0.48	4.14
Total	2.00	1.39	0.00	6.19

Notes: Share of ethnicity in the total population of the region (*Anpassungsschicht*) of residence, 1985 (based on full sample of guest-worker children in SOEP). Data sources: German Socio-Economic Panel (SOEP), Institut für Arbeitsmarkt- und Berufsforschung (IAB).

Child characteristics	Yes	Yes	Yes	Yes	Yes
Parent characteristics	Yes	Yes	Yes	Yes	Yes

Notes: Dependent variables: Panel A: Speaking proficiency: self-assessed speaking ability in German (from 1="not at all" to 5="very well"), normalized to mean 0 and standard deviation 1. Panel B: Writing proficiency: self-assessed writing ability in German (from 1="not at all" to 5="very well"), normalized to mean 0 and standard deviation 1. Panel C: Any school degree: 1 if individual obtained any type of school degree, 0 otherwise. Panel D: At least intermediate school degree: 1 if individual obtained at least an intermediate school degree, 0 otherwise. Size of ethnic group in 1985: log size of ethnic community (individuals of same ethnicity) in region (*Anpassungsschicht*) of residence, 1985. Panels A and B additionally include dummies for year of language assessment. Child characteristics: dummies for birth cohort (2-year intervals), gender, and age at migration. Parent characteristics: the following variables for father and mother, respectively: year of birth and dummies for arrival cohort (2-year intervals), schooling in country of origin (incomplete compulsory schooling and at least compulsory schooling), years of education in 1985, migrant status, and number of mother's children. Standard errors clustered at the region-ethnicity level in parentheses. Significance levels: * p<0.10, ** p<0.05, *** p<0.01. Data sources: German Socio-Economic Panel (SOEP), Institut für Arbeitsmarkt- und Berufsforschung (IAB).
