Germany's Construction Industry: Strong Growth Followed by Stagnation

by Martin Gornig and Hendrik Hagedorn

2011 was one of the construction industry's strongest years of growth since German reunification. For the year as a whole, a nominal increase in construction volume of almost eight percent is expected. The price increase is forecast at over 2.5 percent. Real construction volume in 2011 will be over five percent higher than in 2010.

However, according to current information, we can expect the construction industry to experience a break in growth in 2012. Real construction volumes will barely be higher than in 2011. This development is partly due to the phasing out of economic stimulus packages. Further, the promising announcements of support for energy-efficient modernization as part of the change in energy policy for residential construction has had more of a negative impact on the construction industry. The predicted reluctance to invest will only be overcome if the German government swiftly determines specific financing conditions for the coming years.

The construction volume calculation conducted by DIW Berlin covers production in the construction sector. DIW's analysis of development trends is not confined to the construction industry in the narrowest sense. It also includes other sectors such as steel and light alloy construction, the manufacture of prefabricated buildings, construction metal works, and specific branches of other sectors of the economy which contribute to construction work, as well as planning and other services. The definition used in this report is largely in line with that used for construction investments in the national accounts with the distinction that non-value-enhancing repairs are also included here.¹

Residential Construction: Construction Work on Existing Buildings Dominates

As part of its traditional construction volume calculation, DIW Berlin determines the value of construction of new buildings and construction work carried out on existing buildings (Box 1). The calculations for new building volume are based on detailed model calculations, whereas work on existing buildings is captured using a difference calculation. The volume of work carried out on existing buildings was recently corroborated by extrapolation based on survey results from Heinze GmbH (a leading provider of specialist information for the construction industry).²

According to calculations by DIW Berlin, the new building volume in residential construction was only 31.4 bil-

Box 1

DIW Berlin's Methods for Calculating the Construction Volume**New Building Volume in Residential Construction**

For many years, DIW Berlin has been carrying out annual calculations for the construction sector, taking the development of the new building construction sector as a separate entity. All calculations are based on information provided by construction activity statistics. The key starting variables are based on data on the estimated pure construction costs of approved and completed residential buildings in a specific year. These data are combined to arrive at the total value of new buildings constructed over the period of one year, using a model-based approach and allowing for one-off effects. The statistics on construction backlog are used as a control variable. The costs defined here are the estimated pure construction costs. To calculate the new building volume, therefore, the difference between estimated and actual pure construction costs must be determined. The actual pure construction costs should correspond to the construction industry's production inputs and the manufacturing inputs for new housing. Additional building costs are also incorporated into the calculation using the information available. Apart from development measures and fees, these costs mainly include architectural and planning work. Further factors to be taken into account are personal contributions to the construction project and, where applicable, also undeclared work. In order to acquire information on the extent of the discrepancies between estimated and actual pure construction costs and also on the distribution of planning work between new building and construction work on existing properties, DIW Berlin analyzed a survey conducted among architects and consulting engineers which was developed specifically for this purpose.

Volume of Construction on Existing Buildings

The volume of construction on existing buildings is calculated as the difference between the total construction volume and new building volume. It includes renovation and extension projects as well as modernization and repairs on existing buildings. Using these calculations, it is possible to conduct particularly consistent comparisons over time. The model calculations on the basis of a pure differential approach lack structural information. Therefore, the results from the model calculations based on official statistics are combined with extrapolated results on modernization volumes from surveys. The extrapolation results are drawn from a study carried out by Heinze GmbH. To ensure consistency, the structural information taken from the surveys only relates to the investment part of the construction volume (not including maintenance). Based on these calculations, different structural variables are captured, within the overall construction volume, for construction work on existing properties. Initially, this only applies to 2010. Energy-efficient modernization includes measures from the following product areas: thermal insulation, replacement of windows and outside doors, re-placement of heating systems, and the installation of solar panels. Further, a residential construction project which involves work in at least ten product sectors is treated as a full modernization. In the non-residential construction sector, the threshold is 15 product sectors. Projects involving fewer product sectors are considered to be only partial modernization.

lion euros in 2009.³ Even nominally, this is the lowest value since the mid-1990s (Figure 1). The downward trend in the new building volume in housing construction comes in waves: periods with relatively stable new building volume such as 2001 to 2004 were followed by strong slumps in new building activity. Between 2006 and 2008 alone, new construction output dropped by

almost 30 percent. However, since 2009 there has been evidence of stabilization at a low level. In 2010, there was even nominal growth of almost nine percent boosting new building volume to over 34 billion euros.

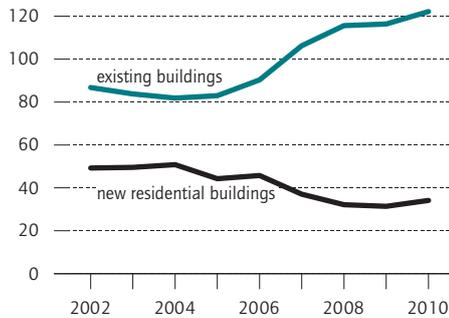

Total residential construction volume, however, has been experiencing positive development since 2006 as a result of a significant increase in the volume of construction work on existing buildings. Whereas, construction work on existing buildings was at around 83 billion euros in 2005, this sum reached in excess of 122 billion euros in 2010, representing a 47 percent increase. This

New building volume is experiencing periodic slumps, while the volume of construction on existing buildings is increasing.

is evidence of the increasing predominance of construction work on existing buildings in relation to the total residential construction output, which increased to 156 million euros in 2010. In that year, construction work on existing buildings made up 78 percent of the total residential construction volume. In 2002, this figure was only 64 percent.

There are a variety of reasons for the increasing share of construction work on existing properties—one important factor is the downturn in new building construction. Demographic developments have led to a decline in the demand for new housing. Furthermore, anticipated returns on investments in residential construction were low, particularly against the backdrop of weak growth in disposable income, which, in turn, led to a reluctance to invest. However, turbulence on the financial markets and the ensuing heightened insecurity led to a re-evaluation of potential returns from housing construction in comparison with other investment options. Not least as a result of this development, 2010 and 2011 saw renewed growth in building construction.

Motivated by a general feeling of uncertainty on the financial markets, private investors have preferred to invest in construction work on existing buildings, which has led to further growth in the volume of this type of construction activity over the past few years. Another important factor in the expansion of construction work on existing buildings is the steadily growing importance of energy-related modernization. This has been triggered partly by support measures established as part of cli-

mate policy and also by rising and highly volatile energy prices. The belief that energy-efficient modernization could combat climate change may also have boosted investment activity. According to analyses conducted by Heinze GmbH, energy-related modernization carried out in 2010 accounted for over a third of all investment in construction work on existing residential buildings.⁴ In the construction volume calculation, this corresponds to a value of over 42 billion euros (Table 1).

It may be assumed, therefore, that the share of energy-related modernization has experienced strong growth in the last few years. Since the middle of the last decade, subsidies have been increased dramatically as part of the support program for energy-related modernization implemented by the German government-owned development bank Kreditanstalt für Wiederaufbau (KfW). Over the past five years, sums amounting to considerably more than one billion euros per annum have been approved for this purpose (Figure 2).

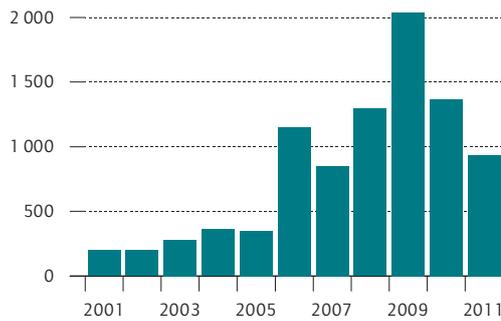

In recent years, the focus of KfW construction sector programs has shifted noticeably towards construction work on existing buildings. Subsidies for residential construction which were available until 2006 as part of the grant scheme for first-home buyers were, in contrast, oriented towards construction of new buildings. This change

in funding policy has contributed to a shift in the distribution of residential construction volume in favor of construction work on existing buildings.

Support Measures Undergoing Change

Over the last two years, there has been a decline in German government subsidization of KfW programs for energy-efficient construction and modernization. The subsidy dropped from over two billion euros in 2009 to under a billion in 2011. Currently, however, there are plans to increase the funds available for KfW programs. In 2012, the government subsidy allocated to the KfW for this sector will be 1.5 billion euros. Additionally, as part of the transformation of energy systems announced by the German government, a further increase in funding is planned. From 2012, subsidies will be transferred to the KfW from the Energy and Climate Fund provided by revenues from trading in CO2 emission certificates. In future, the size of this fund is set to increase with the growing shortage of emission trading rights. For 2013, the German government has already budgeted for 3 billion euros for this purpose. However, the current certificate price is around ten euros, considerably lower than previously anticipated and, also in the medium term, significantly lower emission trade revenues are forecast.

Subsidized Investment as an Early Indicator of Construction Volume

For the most part, the KfW uses government subsidies to reduce the cost of loans. However, this on its own is not enough to guarantee actual demand for financing. Demand is more heavily dependent on a wide range of factors in the construction industry.⁵ The table below presents the actual approved credit volume (irrespective of government subsidization) and the related subsidized investments. The subsidized investments also include construction projects which do not involve energy-related modernization and are, therefore, not eligible for financing. Therefore, investment volume exceeds lending many times over, particularly in the construction of new buildings.⁶

5 The sensitivity of investment activity to government subsidies and any possible principle of additionality are not part of this analysis. Only the development of approved loans over time is taken into account. For forecasting the development of construction volume, the leverage effect of state subsidies is not significant.

6 Further, the size of KfW loan that is eligible for subsidy is restricted, in the case of new buildings, to 50,000 euros and, in the case of construction work on existing buildings, to 75,000 euros.

Table 2 also shows the volume of energy-related modernization in the respective sectors. There is evidence that the subsidized share of the total volume is quite substantial in some areas. In 2010, energy-efficient modernization was carried out on existing residential buildings to a value of more than 42 billion euros against a subsidized investment volume of over five billion euros. The figure for new residential buildings was even higher with a construction volume in 2010 of 34 billion euros against subsidized investments accounting for 14 billion.

It must be taken into account, however, that the investment volume shown here is not directly comparable with the construction volume for the same year as the investments currently only represent planned expenditure to be made over a period of time which cannot be predicted accurately. This means that no precise correlation between subsidy and residential construction volume can be derived from the figures presented here. However, it can be assumed that subsidized construction measures will turn into construction volume in the future. The time frame for this is likely to be considerably longer for new buildings than for construction work on existing buildings.

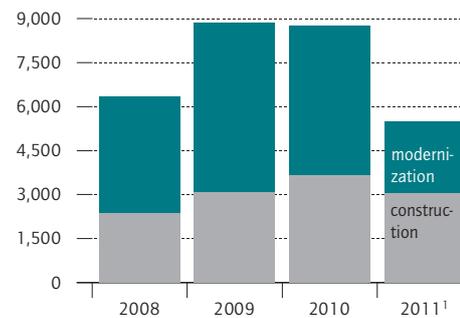

The amount of investment registered by the KfW via loan commitments can, therefore, be ascribed a forecast function. This function also applies to construction on existing properties which makes up the lion's share of construction investments and for which there have been no early indicators so far. The commonly applied bundle of indicators, i.e., building permits, orders received, and order backlog do not give a complete picture of the development of construction activity. The building permits upon which forecasts are based only ever refer to new buildings as only a small proportion of construction projects on existing buildings require permits. Yet the share of residential construction volume accounted for by new buildings is, at 22 percent, relatively low. Data on companies' orders is also only collected for the construction industry as a whole. When compared against the total number of firms operating in the construction industry as a whole, a disproportionate number focus on the construction of new buildings. New residential buildings make up around a third of the construction industry as a whole whereas the volume of work on existing buildings stands at only twelve percent.

Taken on its own, this circumstance does not present any problems for forecasting. However, if the segment of construction work that can be analyzed using indicators covers a different time frame than the rest of construction work, the forecasts based on these indicators will necessarily be distorted. This seems to have occur-

Figure 3

2011 saw a dramatic decline in the number promotional loans approved for modernization.

red with the data on KfW financing. Against this backdrop, in the current situation the KfW data provides valuable additional information for forecasting construction investments.

Bring-forward Effects Play an Important Role

The development of promotional loans summarized in Figure 3 shows that lending for the construction of new buildings has been far more stable than for modernization over the past few years. Notably, in 2011, the number of promotional loans approved for modernization declined sharply.⁷ Against the backdrop of a sound construction economy, this is initially quite surprising. Considering the low interest rate and the favorable labor market situation, the general climate in the construction industry is at least as good as in previous years. This apparent downturn in modernization projects could primarily be traced back to bring-forward effects last year followed by investment reluctance this year because, from 30 June, 2010, subsidies for modernization in compliance with KfW Standard 130 came to an end. For many investors who had planned to carry out modernization according to this standard, this may have acted as an in-

⁷ Although the value for 2011 is only an estimate on the basis of the first three quarters, a comparison of the half year values in Table 2 suggests that there are no significant shifts in the size of the allocation over the course of the year.

centive to apply for funding before the deadline. The increase in government subsidies that is planned for the coming years and the ongoing debate on the introduction of special depreciation have also led to the investment reluctance we are now observing. Both measures hold out the prospect of considerable cost savings for developers if they wait a little with the implementation of energy-efficient modernization. The current stance in the discussion is that the introduction of special depreciation would result in investment costs being cut by 16 percent for rental properties and 35 percent for owner-occupied properties.⁸

A large share of investments recorded by KfW last year may not actually have been implemented until this year, which may have contributed to the continued dynamic growth that has been observed. However, the financing figures for 2011 suggest that we are more likely to see a decline in investment activity next year. If we also take into account that the reluctance to carry out energy-efficient modernization has now spread to other construction areas,⁹ we should expect more subdued growth in the development of investment in construction work on existing residential properties next year.

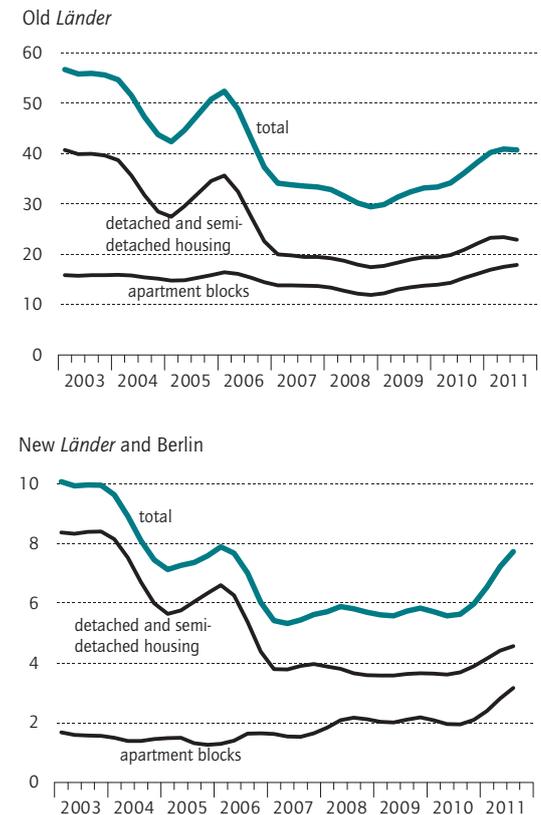

In contrast to the situation with existing buildings, there has only been a slight decline in promotional loan commitments for new buildings this year. However, KfW promotional loan figures also indicate a slight downturn in new building construction activity. However, this will not necessarily have an immediate negative impact next year as the range of investment plans for new buildings is greater than those for construction work on existing buildings.

Building permits, at least, signal continued robust development (Figure 4). 2011 saw an increased number of building permits granted, particularly in eastern Germany. In western Germany, the figures remained at a higher level than in previous years. If we also take into account the sustained favorable financing situation, overall we can definitely expect stable development in the construction of new residential buildings in 2012.

Figure 4

Building Permits for Residential Construction

In 1,000 properties per quarter¹

¹ Seasonally adjusted according to the Berlin procedure (BV4) (methodology and software for decomposing economic time series). Sources: Federal Statistics Office, calculations by DIW Berlin.

© DIW Berlin 2012

In 2011, the number of building permits approved for residential construction increased considerably, particularly in eastern Germany.

Residential Construction Still Showing Little Growth

Despite these indicators of new residential construction, the growth rate of the entire residential construction volume next year is forecast to be considerably lower than in 2011, for which real growth of 6.3 percent is expected. This is primarily due to adverse weather conditions since 2010 was a year with an early onset of another long winter. At the same time, the first quarter of 2011 was marked by backlog effects. The result of this is that the construction volume in 2011 is extraordinarily high, particularly in comparison to the previous year. In view of this special effect, a significantly lower growth

⁸ Neuhoff, K., H. Amecke, A. Novikova, and K. Stelmakh, „Energetische Sanierung: Handlungsbedarf auf vielen Ebenen,“ Wochenbericht des DIW Berlin, no. 34/(2011).

⁹ This applies for instance to full modernizations, which make up around ten percent of investments in existing buildings.

Growth rates for 2012 are expected to be significantly lower than for 2010 and 2011.

rate is to be expected in 2012. Another factor is the above-mentioned reluctance to modernize. This, too, will ensure that construction activities next year will only slowly regain momentum, although the general climate in the construction industry should also be favorable next year. Nevertheless, growth next year will, therefore, probably be only 0.4 percent (Table 3). This estimate differs considerably from the forecasts by other institutes and research groups. The growth rate for residential construction in the Joint Economic Forecast Project Group (Projektgruppe Gemeinschaftsdiagnose) for 2012 was still predicted as 2.3 percent.¹⁰ The German Council of Economic Experts (Sachverständigenrat zur Begutachtung der gesamtwirtschaftlichen Entwicklung) even

forecasts 2.9 percent in its latest report.¹¹ The diverging assessment by DIW Berlin may be due in particular to the more pessimistic estimate concerning construction work on existing residential buildings.

Non-Residential Construction: Economic Stimulus Packages Being Phased Out

According to model calculations by DIW Berlin, the new building volume in commercial and public sector construction has tended to develop differently than that of residential construction (Figure 5). There were various

Work on existing buildings is gaining significance in non-residential construction, too.

phases to the change in new construction activities. From 2003 to 2005, the nominal new building volume for non-residential properties decreased significantly. It fell from 32 billion euros to around 24 billion euros. With the general economic upswing in 2006, however, construction of new non-residential buildings also increased. In 2007 and 2008, growth rates continued to rise and were at around ten percent for each year. Conversely, 2009 and 2010 saw a significant drop in new building volume for non-residential buildings. One decisive factor here was the slump in new construction of production sites in the wake of the crisis in the export sector.¹²

Development of construction work on existing buildings in the commercial and public sectors followed a similar pattern to that of residential buildings. It has been increasing tangibly since 2002. The rise was particularly strong between 2005 and 2008. Even in the crisis year of 2009, construction work on existing non-residential buildings rose slightly again. Growth was extremely positive in 2010, not least thanks to economic stimulus packages in the public sector and support measures in commercial construction. At a level of almost 57 billion euros, the volume of construction on existing buildings reached a record peak.

The gap between construction work on existing and new buildings thus continued to widen also in non-residential properties. The highest increases in the share of construction work on existing buildings are observed during economic slumps. This applies to the period from 2002 and 2005 as well as more recently to the years 2009 and 2010. Although existing buildings only accounted for around half of the construction volume in the commercial and public sectors in 2002, the share of construction work on existing non-residential properties in 2005 was over 60 percent. In 2010, construction work on existing buildings reached a share of more than two thirds of all non-residential construction.

However, the predominance of construction work on existing buildings in non-residential construction is significantly lower than in residential construction, where the share comes close to 80 percent. Similar to in residential construction, the incentive of energy-efficient modernization plays a major role in investment in non-residential construction. If the shares for investments, as calculated by Heinze GmbH, are transferred to the Construction-Volume Account, the volume of energy-efficient modernization in 2010 exceeds 15 billion euros. In other words, more than one in four euros invested in constructed work on existing non-residential buildings is spent on energy-efficient modernization.

Commercial Construction Stagnates, Public Sector Construction Declines in 2012

The significance of modernization measures in commercial construction is relatively low, however. Here, the share of overall construction work on existing buildings was only 21 percent. Apart from the funding allocated in the first economic stimulus package, these measures are not state funded in commercial construction, either. Rather, it is energy prices and expectations regarding future development that are behind modernization being considered a good investment. But this factor alone does not determine the development of non-residential construction. In structural terms, traditional non-energy-related areas still carry significantly more weight. In view of the faltering economy and uncertainty due to the debt crisis, no increase in investment is to be expected here in the foreseeable future, however. Although building permits showed a relatively stable development in 2011, it still remains to be seen whether the projects approved will also come to fruition in these times of economic uncertainty (Figure 6).

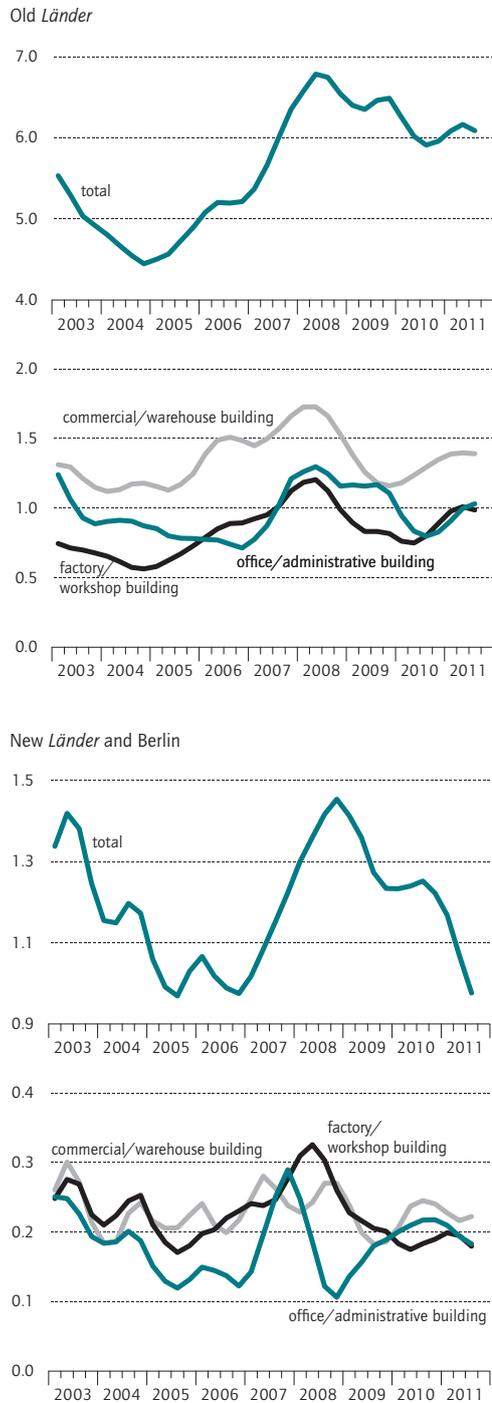

Unlike in the commercial construction sector, subsidization of building modernizations is a significant factor for public sector construction. Here, however, programs

Particularly in eastern Germany, the phasing out of the economic stimulus package is noticeable from the volume of building permits.

Table 4

KfW's Program for Energy-Efficient Construction in the Public Sector (Existing Buildings)

Loan commitments in million euros

	Total lending	Investment volume	Modernization volume (nominal)
2007	28	57	
2008	85	133	
2009	145	229	
2010	106	206	9,070
2011 ¹	108	145

Compared to the total modernization volume, the support program for energy-efficient construction is of only minor significance.

implemented by the KfW development bank appear to have played only a minor role over the past few years. As shown in Table 4, subsidized investments make up only a small fraction of all the modernization measures carried out and consequently also give very little indication of further development. The share seems to be low partly because the economic stimulus packages acted as the decisive incentive to modernize in public sector construction over the past few years. Distributed over the last three years, an investment package of over ten billion euros was provided for modernization.¹³ A substantial part of this investment program was not implemented until 2011.

Since these subsidies earmarked for municipal budgets will no longer be available as of next year, there is likely to be a significant decline in modernization of buildings in the public sector then. Instead, state-funded investments are set to concentrate on areas where there is room for improvement. Yet, no real revival of public investments is to be seen at present. Rather, it is to be assumed that despite this year's economic upturn, many local authorities are unlikely to initiate many additional investment projects next year. Generally, the heterogeneity of the local authorities and their notorious financial constraints cannot be ignored. Specifically in eastern Germany, we have not seen an extensive improvement in the financial situation of the local authorities this year due to the low enterprise density.

Box 2

DIW Berlin's Methods for Forecasting the Construction Volume

The forecast for development trends in construction volume is embedded in the macroeconomic forecast by DIW Berlin¹. Consequently, in an initial step, projections of construction investments are carried out, which can then be presented consistently in the system of national accounts. Indicator-based statistical models are used for forecasting construction investments. The volume of commercial buildings, for instance, is predicted by performing a regression with an autoregressive term and lagged values of the pertinent indicator. The forecast equation is generally expressed as follows:

$$y_t = \alpha + \sum_{i=1}^n \beta_i y_{t-i} + \sum_{j=1}^m \gamma_j x_{t-j} + \varepsilon_t$$

where y_t is the value to be predicted, x_t the indicator, and ε_t the statistical error term. The parameters α , β_i , and γ_j are estimated.

The delay lengths n and m (in years) are determined using the autocorrelation and/or cross correlation function. The various specifications are also evaluated according to the information criteria available.

The forecast quality is checked using ex-post forecasts. The specifications with the least square deviation of the forecast values from the actual values are then used for the forecast.

The backlog of orders and volume of building permits in residential construction have proven to be suitable

indicators for forecasting residential construction, while for commercial construction, investment in equipment, capacity utilization, and orders and/or building permits for non-residential properties are taken into consideration.² On the other hand, construction in the public sector is not determined using indicators, but it is derived from the forecast of government accounts, bearing in mind both government revenue and economic stimulus packages.

The individual indicators sometimes lead to very different results. Moreover, construction investment is largely shaped by legislative frameworks such as the discontinuation of the grant scheme for first-home buyers, changes to which can only be inadequately depicted in these models. Therefore, these statistical procedures serve only as an indicator for the forecast. The picture for the individual aggregates of the construction investment is then matched with the other aggregates of the national accounts in a further step.

In the final step, the forecast results are transferred to the model of the construction volume calculations. Additionally, also taking into account the characteristics of non-invested construction work in the economic cycle, development trends on the demand side are taken into consideration. More detailed information on building permits and the order backlog is used to differentiate according to further structural characteristics. This makes it possible to predict different developments between eastern and western Germany and between individual production groups, such as the construction sector as a whole and the finishing trade.

¹ On the method, see, for example, Rapach, D.E. and M.E. Wohar, "Forecasting the Recent Behaviour of U.S. Business Fixed Investment Spending: An Analysis of Competing Models," *Journal of Forecasting* (2011): 26, 33-51; for recent findings, see Fichtner, F., S. Junker, K. Bernoth, K. Brenke, C. Dreger, A. Erdmann, C. Große Steffen, H. Hagedorn, B. Jochimsen, and K. Pijnenburg, "Herbstgrundlinien 2011," *Wochenbericht des DIW Berlin*, no. 40 (2011).

² See Döpke, J., U. Fritsche, J. Gottschalk, E. Langmantel, B. Loose, and C. Schumacher, "Indikatoren zur Prognose der Investitionen in Deutschland," *Kieler Arbeitspapier*, no. 906, (Kiel: 1999).

The weakness in public sector construction is also evidenced by building permits. For the whole of Germany, their value in the first half of 2011 was 20 percent lower than that of the previous year. This decrease is also reflected in the index for building permits for all non-residential construction. In eastern Germany, the decline was particularly noticeable. Thus, prospects for public

sector construction in the East are bleak. In the West, conversely, in view of constant building permit figures, it can be expected that at least to some extent the investments which have been withheld will now be forthcoming. Nevertheless, for western Germany, too, a decline is to be expected next year.

The construction volume for non-residential buildings is expected to increase again in 2011 by a total of 3.6 percent. However, a decline in public sector construction and the cautiousness of investors in commercial construction will have an impact in 2012. The real decline to be seen then is estimated at around half a percent.

Strong Overall Growth in the Construction Industry in 2011

2011 will prove to be one of the years with the strongest growth for the construction industry since reunification. For the year as a whole, growth of the construction volume is forecast at a nominal 7.8 percent. The annual average price increase is expected to be over 2.5 percent. This means the real construction volume will increase by over five percent in 2011. This favorable development stems from an overlap of positive impetus for growth from all areas of the construction sector. Not only does residential construction continue to be developing very positively, but commercial construction is also currently still supported by the economic outlook. In public sector construction, the remains of the economic stimulus packages are already having a procyclical effect.

The overall growth rate in the old Länder is somewhat higher. Primarily because of less dynamic growth in residential construction, development in the new Länder in 2011 remains below average. But here, too, real growth will be at around 4.5 percent.

In 2011, the construction sector as a whole may also finally profit again from growth of the construction volume. After a decline in the past few years, the construction sector should show above-average real growth at almost six percent. In the finishing trade, on the other hand, the upward trend that began in 2010 continues.

Stagnation Expected in 2012

Most of the current forecasts for investment in construction next year anticipate a continuation of the growth process, albeit at a lower level. The German Council of Economic Experts predicts a real growth rate of 1.5 percent for 2012, while the Joint Economic Forecast expects growth of 1.3 percent.¹⁴ These relatively optimistic estimates can be largely attributed to the indicators used in these reports—namely, details of building permits and orders received by larger companies in the con-

struction industry. Both are areas that reflect the development of new buildings above all. The narrow focus on new building activity and the construction industry is an increasingly poor indicator of the overall development of construction investment and/or the construction volume, however, since construction work on existing buildings is becoming increasingly important and is subject to other development trends.

Taking better account of the data on KfW financing could bring an improvement in forecasting. In the past few years, KfW loans have gained growing importance and now play a role in a significant share of all construction work carried out. Consequently, they are also of increasing interest for construction industry forecasts. One decisive factor here is that the statistics on financing by the KfW also provide information about planned construction measures on existing buildings. Therefore, they represent a source of information that provides more content than existing sets of indicators. The lead time of the plans to invest approved by KfW can sometimes be over a year.

On the basis of the expanded set of indicators and according to the information available at present, a break in the growth process of the construction industry is expected in 2012. Overall, a stagnation of the real construction volume is predicted for 2012. On the one hand, this is accounted for by the general slowing of the economy in Germany. On the other hand, the promising announcements of support for energy-efficient modernization as part of the change in energy policy are currently causing a reluctance to make investment plans. This reluctance to invest in measures for energy-efficient modernization in particular will only be overcome if the German government swiftly determines the specific financing conditions for the coming years.

FIVE QUESTIONS TO HENDRIK HAGEDORN

» We Need Clarity on Financing Conditions«

the end of the economic stimulus packages in particular. The residential construction situation is a little different as subsidies for this sector come mainly from Germany's government-owned development bank, KfW. This support program has reached a turning point and is at an all-time low, which has resulted in people being somewhat reluctant to apply for financing from this source at the moment. This will have a knock-on effect into next year as the reluctance to apply for support will translate into less construction work at the beginning of next year.

1. Mr. Hagedorn, how has the German construction industry developed over the past few years and what is the current situation? 2011 has been a year of exceptionally strong growth for the construction industry. There will be real growth of over five percent. The fact that 2010 was not a particularly good year because of the very early onset of winter also played a part in this development. There was, therefore, a lot of catching up to be done in 2011. This alone led to a marked increase in the growth rate. We are also seeing increased investment in construction triggered, to a large extent, by the financial crisis. Investors are trying to invest more in tangible assets and less in financial products. The construction industry is obviously benefiting from this.
2. How will the construction industry develop over the next year—Will the current trend continue, or do you foresee a slump? We don't forecast a slump, but expect zero growth next year which is nonetheless a very good result. There is still interest in investing in housing and we expect this to continue into next year. However, there won't be the same weather-related impetus we experienced this year. Furthermore, there has been a change in policy concerning financing programs, which we believe is likely to have a somewhat negative impact on the construction industry next year.
3. What impact has the phasing out of the economic stimulus packages had? The phasing out of the economic stimulus packages has had a particularly negative impact on construction in the public sector. We will see a marked decline in this sector next year owing to
4. Does this mean that the planned support measures should be implemented as soon as possible? Above all, we need clarity when it comes to financing conditions. Once we have that clarity and property developers are able to adjust to the financing conditions for the next two to three years, then the reluctance I mentioned should dissipate. However, anyone who expects the conditions to improve in the future obviously isn't going to start a construction project right now. On this subject, there is currently an ongoing debate about the introduction of special depreciation. The process is stuck with a mediation committee and the outcome is, as yet, unclear. While this situation continues, a lot of potential home builders will hold back.
5. To what extent is the construction industry actually reliant on further support measures? Fundamentally, the construction industry obviously doesn't depend completely on this type of financing. Even the loss of some of these support measures would not lead to an overall downturn. However, these programs are welcomed by the construction industry. The finishing trade in particular profits enormously from the modernization projects being implemented in Germany. From a macroeconomic perspective, however, these programs should be viewed very critically: while construction projects are being subsidized, somewhere else, money is lost in the system and that costs jobs. This means that for all jobs that are created in the construction industry, a lot of other jobs we don't know about fall by the wayside.

Interview by Erich Wittenberg.

German Industry—a Tower of Strength?

by Dorothea Lucke

By the summer of 2011, Germany industry was back at levels last achieved before the economic crisis, thanks to continuous growth in production since early 2009. The recovery was driven by strong domestic and foreign demand for German capital and intermediate goods. However, the Ifo Business Climate Index, which has contracted since July 2011, and fewer orders suggest that industrial production will decline by the end of 2011. The duration and intensity of the slowdown will depend not least on how quickly policy-makers take convincing measures to resolve the debt crisis in the eurozone and thus allay widespread uncertainty among investors and consumers.

Demand for industrial products increased in the first three quarters of 2011 by ten percent over the previous year. While the impetus at the beginning of the upturn came mainly from emerging countries, this year domestic demand and demand from other countries in the eurozone contributed almost as much to growth as demand from outside the eurozone. This surge in demand has allowed industry (mining and quarrying, manufacturing, energy supply) to increase production by ten percent (Tables 1 and 2, and Figure 1) in the same period.

As a result of the as yet unresolved debt crisis in the eurozone, DIW Berlin forecasts a period of stagnation for Germany and the eurozone in the winter months from 2011 to 2012. Assuming it will be possible to significantly reduce investors' uncertainty in early 2012, then gross domestic product in the eurozone will develop more dynamically again.¹ This scenario provides the framework for DIW Berlin's industry forecast (box).

Capital Goods: Peaked in Summer 2011

Investment activity this year was stimulated by low interest rates and positive prospects for global economic development. As a result, companies quickly caught up on demand for investment caused by the economic crisis. Domestic demand for capital goods² from Germany rose in the first three quarters by 15 percent over the previous year. Demand from the eurozone increased by twelve percent and demand from the non-eurozone increased by as much as 25 percent, so capacity utilization among capital goods producers in Germany increa-

¹ Fichtner, F. et al., „Herbstgrundlinien 2011,“ DIW Wochenbericht, no. 40(2011).

² As the manufacture of motor vehicles (Group 29.10 in the Classification of Economic Activities, Edition 2008 (WZ 2008)) is counted as capital good, although motor vehicles are consumer durables, since the changeover in 2005 the Federal Statistical Office publishes additionally the aggregate „Capital goods excluding 29.10.“ The figures listed refer to this aggregate.

Industrial production has reached the same level it was at before the crisis.

sed beyond the long-term average.³ The situation is similar in the manufacturing sector as a whole.⁴ New orders have increased in many industries to a level that leaves companies considering investing in expansion. However, domestic and foreign mood indicators⁵ signal a significant deterioration in overall economic development for a number of months, probably leading to orders being cancelled. Companies will extend the processing time of order backlogs and delay expansion projects. It can therefore be assumed that domestic and foreign demand for German capital goods will decline significantly during the winter months.

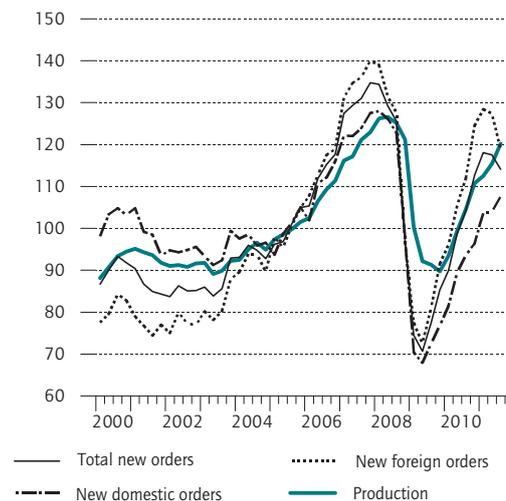

These developments are particularly evident in the manufacture of machinery and equipment, the largest capital goods sector (Figure 2). Due to an increase in demand of 20 percent in the first three quarters compared to the same period in the previous year, seasonally adjusted production figures increased strongly again in the third quarter; they are now 17 percent higher than in the previous year.

New orders of machinery and equipment from the non-eurozone have been declining for two quarters now, however, showing that the investment cycle had peaked there. In contrast, seasonally adjusted new domestic orders in the third quarter of 2011 rose compared to the previous quarter, albeit with declining monthly figures since their highest value in July. Due to the steadily deteriorating mood indicators, it can be assumed that weaker demand for machinery and equipment is not a

Figure 2

New Orders and Production in the Manufacture of Machinery and Equipment¹

© DIW Berlin 2012

short-term or random phenomenon, but more a sustained decline in demand.

Signals coming both from abroad and at home would suggest lower production of machinery and equipment at the end of the year and into the first quarter of 2012. After that, production should increase again. Compared to the previous year, an increase in production of almost 14 percent is expected in 2011, and 1.5 percent for the coming year (Table 3).

Manufacture of motor vehicles, trailers and semi-trailers includes the manufacture of cars and commercial vehicles, and related parts industries (Figure 3). While the entire industry is allocated to the main industrial grouping “capital goods”, only commercial vehicles are actually capital goods as such. One indicator of the development of the commercial vehicle sector is demand for and production of bodies for motor vehicles, trailers and semi-trailers (WZ 2008, 29.20). New orders received from the non-eurozone (the eurozone, domestic demand) in the first three quarters of this year were almost 70 percent (20 percent, 17 percent) up on the previous year. Demand peaked in the second quarter, while production continued to increase. Production is expected

Box

DIW Berlin's Industrial Conference

The industry forecast by DIW Berlin formed the basis for discussions at DIW Berlin's Industrial Conference held in Berlin on October 27 and 28, 2011. The conference brought experts from companies and associations together to compile with DIW Berlin a detailed economic picture of industry in Germany and other key countries. At this year's conference, association experts outlined a significantly more positive image of industrial activity in the coming year than DIW Berlin. The current very high degree of uncertainty about overall economic development prompted us to leave the two viewpoints side by side. In this report, DIW Berlin presents its industry forecast and explains its differences to the outlook proposed by association experts.

Table 3

Industrial Production in Germany¹

Changes over the previous year in percent

In 2012, production will not exceed levels from the previous year.

to follow demand after a brief delay, so a decline in production is likely in the fourth quarter of 2011.

Domestic and foreign demand for cars, which is dependent on private consumption, increased sharply last year but has tailed off since the beginning of 2011. This is not surprising in view of weak consumer development in many key markets and consumers' uncertainty due to the debt crisis. This makes the sharp rise in production of motor vehicles and engines all the more astonishing. Production in the first three quarters of 2011 was a good 16 percent higher than in the same period last year. In the coming months, production is expected to be adjusted in line with demand, meaning a significant drop in production.

This development in the car and the truck division will also result in production constraints in the parts industry, and consequently, overall growth for the current year is still expected to be over 14 percent. Since the decline in production will last until at least spring, growth in the vehicle construction industry is only expected to be about one percent for the coming year.

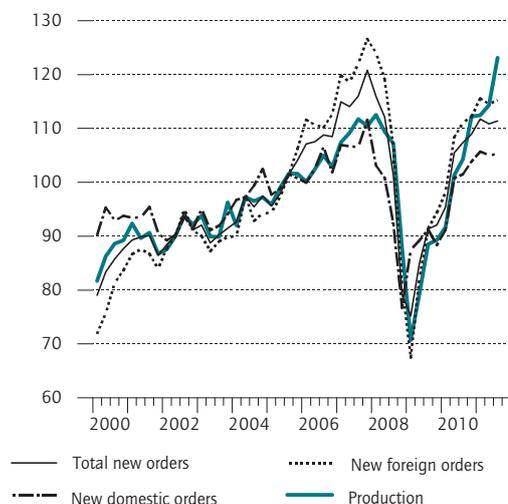

Intermediate Goods: Intermediate Goods Producers Come Up Against Flagging Investments

Intermediate goods produced in Germany are mostly used for capital goods both at home and abroad. Consequently, the demand for intermediates is substantially dependent on demand for capital goods—equipment and buildings. Demand for intermediate goods from abroad surpassed its peak in the first quarter of 2011. This suggests—as does the decline in foreign demand for capital goods from Germany—an end to the investment boom abroad. Domestic demand for intermediate goods in the third quarter of 2011 declined for the first time in line with domestic demand for capital goods. Towards the end of the year, demand for intermediate goods will fall further. This downward trend is reinforced by the fact that impulses from the construction industry, which has developed dynamically this year, are slowly tapering off. According to the trend of demand, production of intermediate goods will decline during the winter months, after which it should recover again.

The manufacture of basic metals (Figure 4) supplies, in particular, the automotive and construction industries, and also the manufacture of machinery and equipment and of tubes and pipes. In 2009, it benefited from the economic policies aimed at supporting its customer industries after the economic crisis, and last year also from the high demand for capital goods at home

and abroad. A rapid increase in demand has driven up the price of metals. In order to preempt further price increases, customer industries and distributors have filled their warehouses with metallic products. Due to the deterioration of their business prospects over the course of this year, they are now attempting to reduce these warehouse stocks. As a result, the trend of demand for basic metals in the first three quarters of 2011 (+2.5 percent) was weak compared to production in customer industries. Production will therefore be adjusted and restricted significantly in the last quarter of 2011. It will also still remain at a low level in the first quarter of 2012. With an improvement in economic conditions in the industry over the next year, manufacture of basic metals will also be revived. The annual average for 2011 will still represent production growth of 8.1 percent due to the high level at the beginning of the year; in 2012, it is more likely to be 0.5 percent.

New orders in the manufacture of chemicals and chemical products (Figure 5) have been declining since the second quarter of 2011, and companies have responded with production cuts. Since the chemical industry generally has a head start on the development of industry as a whole, this is a very clear indication that German industry reached the peak of its business cycle in the third

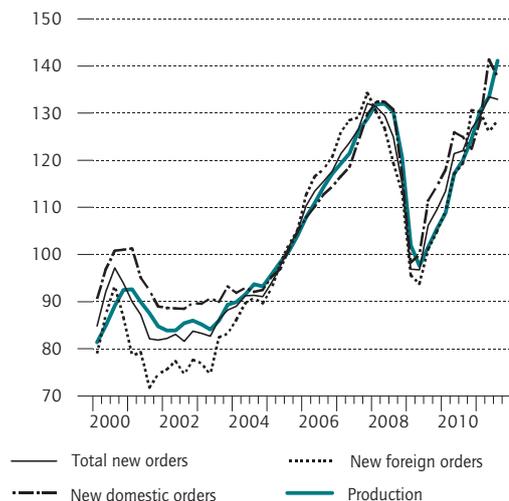

quarter. Equally, customer industries at home and abroad will restrict production in the fourth quarter, leading to a significant decline in production in the chemical industry. As a result, average growth for 2011 will be limited to 1.6 percent. While it is assumed that a recovery in the chemical industry will occur early next year, a decline in the annual average production for 2012 of 1.5 percent compared to 2011 is still expected.

The manufacture of electronic and electrical equipment (Figure 6) produces intermediate, capital, and consumer goods. The corresponding group of customers determines the economic development of the various sectors. Among intermediate goods, electronic components are significant because they are used in the entire capital goods industry and, as a result, demand for components reflects the situation in the capital goods industry. In the first three quarters of 2011, demand from the non-eurozone was seven percent below the same period last year. Domestic orders have risen by 45 percent, but they have also now reached their peak. Further evidence of the decline in this market comes from the decrease in prices of electronic components, which was stopped in 2010 due to high demand.

The production of electronic components rose in the first three quarters by 38 percent over the corresponding period last year, and, seasonally adjusted, it rose again in the third quarter, compared to the previous quarter. Given the now declining new orders and the expected development in customer industries, also the production of components will recede in the fourth quarter of 2011.

In the durable goods sector of the manufacture of electronic and electrical equipment, the manufacture of household appliances carries the greatest weight. Demand for household appliances from the eurozone (minus seven percent in the first three quarters compared to the same period last year) is characterized by weak consumption there. Strong domestic demand (almost six percent) and non-eurozone demand (just over eight percent) in the same period led to an increase in production up to current levels representing two percent over the previous year.

Overall, the manufacture of electronic and electrical equipment with its intermediate and capital goods sectors benefited greatly from brisk domestic investment activity. This year, it will achieve growth of 15 percent.

Due to the expected drop in production in the fourth quarter and the likelihood that it will not increase again until spring, the forecast for annual average production in 2012 is that it will decrease by half a percent.

Consumer Goods: Weak Development Due to Strong Dependence on Consumption in the Eurozone

The German consumer goods industry is more oriented to the eurozone than the capital and intermediate goods industries.⁶ Consequently, their development is mainly influenced by private consumption in the eurozone. In Germany, positive employment and income growth has supported consumption this year, although the debt crisis led to a reduction in income expectations and therefore to cuts in consumer spending throughout 2011. In the rest of the eurozone, the current and expected economic situation curbs demand for consumer goods. As a result, production in the consumer goods industry increased by only 3.5 percent in the first three quarters of this year compared to the same period last year. Since cost-cutting measures introduced by many governments in the eurozone will lead to a weakening of private consumption, rather poor development is expected for the fourth quarter of 2011 and for the coming year.

The manufacture of food products and beverages (Figure 7) is the largest sector within the consumer goods industry at 42 percent. In the first three quarters of 2011, real domestic sales increased again in this sector after years of declines. However price increases curbed this⁷ dynamism. Due to strong demand from the non-euro area (+20 percent in the first three quarters compared to the same period last year), there, manufacturers were able to impose hefty price increases of ten percent, whereas this was only possible to a lesser extent in the eurozone and even less successfully in Germany. In the third quarter, seasonally adjusted real sales in all three economic areas fell compared to the previous quarter and the annual average for 2011 will only be 0.6 percent above last year's level. Next year, growth is expected to reach approximately one percent.

⁶ It has an export ratio of about 30 percent, and of these exports around 60 percent go to the eurozone.

⁷ For example, producer prices for cereals in the first three quarters of 2011 increased by 65 percent over the same period last year.

the associations expect industrial production to grow by just over two percent next year. DIW Berlin’s industry forecast, however, predicts that the uncertainty of economic entities and the deterioration of business prospects due to the continuing debt crisis in the eurozone will lead to a stronger downward trend. Industrial production will only grow again when the mood improves and economic prospects brighten again early next year. The 2011 annual average of industrial output will be almost 8 percent higher than in 2010, and next year this level is unlikely to surpass the level from 2011.

Energy: Assessment of Energy Production through Renewable Energies is Incomplete

In the main industrial grouping “energy”, energy supply is the most relevant sector at 86 percent. Its production index was severely affected by the shutdown of nuclear power plants in Germany after the Fukushima reactor accident in March 2011. Energy generation from industrial power plants and renewable energy systems is not included in this production index.⁸ Since their share in energy production is constantly increasing, the production index increasingly misrepresents actual domestic energy supply. Forecast declines in the production index of domestic energy supply of almost 8.6 percent this year and 1.5 percent next year are thus also likely to underestimate the development.

Outlook

The dynamic development of industrial production by the third quarter of 2011 is the result of strong domestic and foreign demand for German capital and intermediate goods. New orders, however, show that demand has already reached a peak and industrial activity is expected to slow towards the end of the year. Experts from

Financial Integration and Macroeconomic Stability: What Role for Large Banks?

This study assesses how banking sector integration and especially cross-border lending affect macroeconomic stability. I use a two-country general equilibrium model with heterogeneous banks that are hit by idiosyncratic shocks. According to the concept of granularity, idiosyncratic shocks to large firms (or: banks) do not have to cancel out under a skewed distribution of firm sizes. Given the highly skewed distribution of bank sizes, macroeconomic stability may thus be affected by shocks to large banks. Hence, to grasp the impact of financial liberalization on aggregate fluctuations, the presence of large banks as measured by high concentration in the banking industry has to be accounted for. I study the role of different forms of banking sector integration - i.e. arms-length crossborder lending versus lending via foreign affiliates - for the stability of aggregate lending. I find that banking sector integration decreases the aggregate volatility of lending due to intensified competition. The model implies that cross-border lending is more stable under lending via foreign affiliates than under arms-length cross-border lending.
